Glossary of Terms

Aquifer Exemption	The process by which an aquifer, or portion of an aquifer, that meets the criteria for an underground source of drinking water, for which protection under the Safe Drinking Water Act has been exempted under the criteria in 40 CFR 146.4. Injection of fluids through a Class I, II, or III injection well into any aquifer that meets the classification as a USDW requires a demonstration that the aquifer is not currently serving a drinking water system and is not expected to do so in the future.
Bleed	A small flow of water from a process flow stream for the purpose of affecting process pressure.
Brine Solution	A concentrated solution containing dissolved minerals (usually greater than 100,000 mg/l), especially chloride salts.
Central Processing Plant	The main processing facility that typically includes the ion exchange system, elution and precipitation circuits, settling and holding tanks, dewatering equipment, vacuum dryer and effluent control systems.
Confining Bed (layer)	A geologic formation, group of formations, or a part of a formation of low permeability above and below an aquifer that confine groundwater to flow within the aquifer.
Elution	The process of extracting (or eluting) one material from another by washing with a solvent (eluant) to remove adsorbed material (such as uranium) from an adsorbent such as an ion exchange resin.
Excursion	Any unwanted and unauthorized movement of a recovery fluid detected and confirmed at the monitoring well ring.
Facility	Buildings, grounds, equipment, instruments, furniture, vehicles, and scrap.
Ion Exchange	A chemical process used to recover uranium from solution by the exchange of dissolved uranium ions between a lixiviant (leach solution) and a solid, either a mineral surface or, more commonly, a synthetic polymer resin
Injection Well	A well in which fluids are injected rather than produced, the primary objective typically being to maintain reservoir pressure. Two main types of injection are common: gas and liquid. Liquid-injection wells are common offshore in the oil and gas industry, and in solution (in-situ) mining.
In Situ Leach	The in-place recovery of a mineral resource without removing overburden or ore. This method of mining is typically accomplished by installing a well and recovering the resource directly from the natural deposit by exposing it to the injection and recovery of the lixiviant that causes leaching, dissolution and recovery of the mineral. The term in situ leach is synonymous with the term in situ recovery (ISL) for the purpose of this document.
Lixiviant	A leachate solution pumped underground to recover the uranium from the ore

	body.
Monitor Well	A well used to obtain water quality samples or measure groundwater levels; also referred to as Monitoring Well
Ore Horizon	An interface indicative of the uppermost position of an ore body in a stratigraphic sequence.
Picocurie	One one-trillionth (1/1,000,000,000,000) of a Curie: a measure of radioactivity based on the observed decay rate of approximately one gram of radium. The Curie was named in honor of Pierre and Marie Curie, pioneers in the study of radiation.
Pore Volume (PV)	Volume of water required to replace the water in the volume of aquifer that was mined.
Production Well	Also known as 'extraction well' for in situ recovery, usually located in the center of a 5 or 7 spot well pattern; used to pump the metal-laden solution to the surface for further treatment.
Radionuclide	An unstable form of a nuclide that decays or disintegrates spontaneously emitting radiation. Nuclide: a general term applicable to all atomic forms of an element. Nuclides are characterized by the number of protons and neutrons in the nucleus as well as by the amount of energy contained within the atom.
Safe Drinking Water Act (SDWA)	The main federal law that ensures the quality of Americans' drinking water. The SDWA sets the framework for the UIC Program to control the injection of fluids. EPA and states implement the UIC Program, which sets standards for safe injection practices and bans certain types of injection.
Satellite Plant	A remote plant consisting of an ion exchange system, pumps, reverse osmosis unit and transportation vehicles (tanker trucks) to transport loaded resins to the central processing plant.
TENORM	Technologically Enhanced Naturally Occurring Radioactive Material
Thermoluminescent Dosimeters (TLD)	Dosimeters made of certain crystalline materials that are capable of both storing a fraction of absorbed ionizing radiation and releasing this energy in the form of visible photons when heated. The amount of light released can be used as a measure of radiation exposure to these crystals.
Underground Source of Drinking Water (USDW)	An aquifer or portion of an aquifer that supplies any public water system or that contains a sufficient quantity of ground water to supply a public water system, and currently supplies drinking water for human consumption, or that contains fewer than 10,000 mg/l total dissolved solids and is not an exempted aquifer.
Yellowcake	A mixture of uranium oxides that can vary in proportion and in color from yellow to orange to dark green (blackish) depending on the temperature at which the material was dried (level of hydration and impurities). Higher drying temperatures produce a darker, less soluble material. Yellowcake is

commonly referred to as U3O8. This fine powder is packaged in drums and sent to a conversion plant that produces uranium hexafluoride (UF6) as the next step in the manufacture of nuclear fuel.

Section 1.0 - Introduction

1.1 Background

Powertech (USA) Inc. (henceforth, Powertech (USA)) submits this Plan of Operations (POO) as applicable to subparts of 43 CFR § 3809 of the federal requirements to develop and operate the Dewey-Burdock Project ("Proposed Action" or "PA") using in situ leach (ISL) methods to recover uranium. The following Plan of Operations describes the Proposed Action and its environmental setting within the proposed action area (PAA) that includes northwestern Fall River County and southwestern Custer County, South Dakota. Powertech (USA) believes this POO provides sufficient information and descriptions for the Bureau of Land Management (BLM) to make a determination that the Proposed Action will not result in unnecessary or undue degradation of public lands. A request for occupancy is provided in Appendix 1.1-A.

The PA will extract and process uranium which is produced as an oxide, with trade names of "Yellowcake and U_3O_8". Uranium is used as fuel to produce electricity in nuclear power plants. In the United States, 20 percent of the electric power supply is produced by nuclear power. There are currently 104 active licensed nuclear power plants in the US and there are more than 30 nuclear power plants planned for construction in the United States. Nuclear power plants produce minimal amounts of greenhouse gases, thereby decreasing the overall carbon footprint of energy production in the United States. In the United States, the operating nuclear power plants currently have annual requirements for about 54 million pounds of uranium in the form of an oxide. The Proposed Action is planned to produce one million (1,000,000) pounds of U_3O_8 annually for seven years with the potential for extending the production life to 20 years with additional resource development in the area. Currently domestic uranium production is 4.5 million pounds of U_3O_8, with the remainder of the necessary uranium being imported from other countries. The Proposed Action's uranium production will contribute significantly to the energy independence of the United States and will contribute significantly to reducing carbon dioxide and nitrogen oxide emissions in the United States.

1.2 Proposed Surface Disturbance

The EPA method used to determine the AOR for injection wells uses a minimum fixed radius of ¼ mile. The fixed radius AOR for this site specific area permit includes the project area (i.e., the well fields) plus a circumscribing area of no less than 1 mile. The following sections summarize the activities planned by Powertech and are described utilizing the 1.2-mile external boundary chosen based upon the larger AOR required by the Nuclear Regulatory Commission (NRC).

Due to the nature of ISL production, minimal and intermittent surface disturbance will be associated with the project, and will be mainly associated with the central processing plant (CPP), ponds, maintenance and office areas. Additional intermittent disturbance occurs in the well fields, which includes well drilling, pipe installations, and road construction; however, well field disturbances and impacts affect a relatively small area and are short-term.

Surface disturbances associated with the construction of the CPP, office and maintenance buildings, and well field header houses will be for the life of the PA. Topsoil will be stripped and stockpiled from these areas prior to construction. Disturbances associated with the well field drilling and pipeline installation are limited and will be reclaimed as soon as possible after these components are completed. Surface disturbance associated with the development of access roads will occur at the project site; topsoil will be stripped from the road areas and stockpiled prior to construction.

While, the PAA encompasses 10,580 acres, the land potentially disturbed by the PA will be approximately 68 acres (facilities, piping, ponds, well fields and roads) the year proceeding operation commencement. The disturbed area during the life of the project (production to restoration) is estimated to increase over time to a maximum of 108 acres depending on disposal method permitted. If the maximum area for land application of treated wastewater is included in the footprint of the PA (Exhibit 1.1-1), then an additional maximum of approximately 355 acres would be affected by the PA for most of the project life. With the use of land application, the maximum potential disturbance at any given time is expected to be 463 acres. The permitting of deep disposal wells as an alternative to land application would decrease the operation's footprint considerably (Exhibit 1.1-2). The total amount of BLM managed land expected to be disturbed by Powertech (USA) over the life of the PA is approximately 13 acres (Figure 1.2-1).

Figure 1.2-1 displays the locations of uranium ore bodies and a proposed main access road and overhead electric line located on BLM managed lands. These are expected locations of major operational infrastructure that will result in surface disturbance during development of the PA. Also included on this figure is a table showing the total expected surface disturbance acreage on BLM lands associated within the PA. The total estimated BLM surface disturbance calculations take into account all surface disturbance activities throughout the life of the project on BLM managed lands.

The total amount of BLM managed land expected to be disturbed by Powertech (USA) over the life of the PA is approximately 13 acres (Figure 1.2-1). The derivation of this estimate of total surface disturbance acreage takes into account several assumptions. These assumptions include:

- The estimate of BLM surface disturbance is based on the construction and development of all uranium ore bodies within BLM managed lands associated with the PA.
- Partial on-going surface reclamation of disturbed areas immediately following construction has not been considered in the total BLM surface disturbance calculation.
- Not all of the BLM surface disturbances are expected to be active at any one time due to phased development.
- Header house surface disturbances are included in minor road calculations.

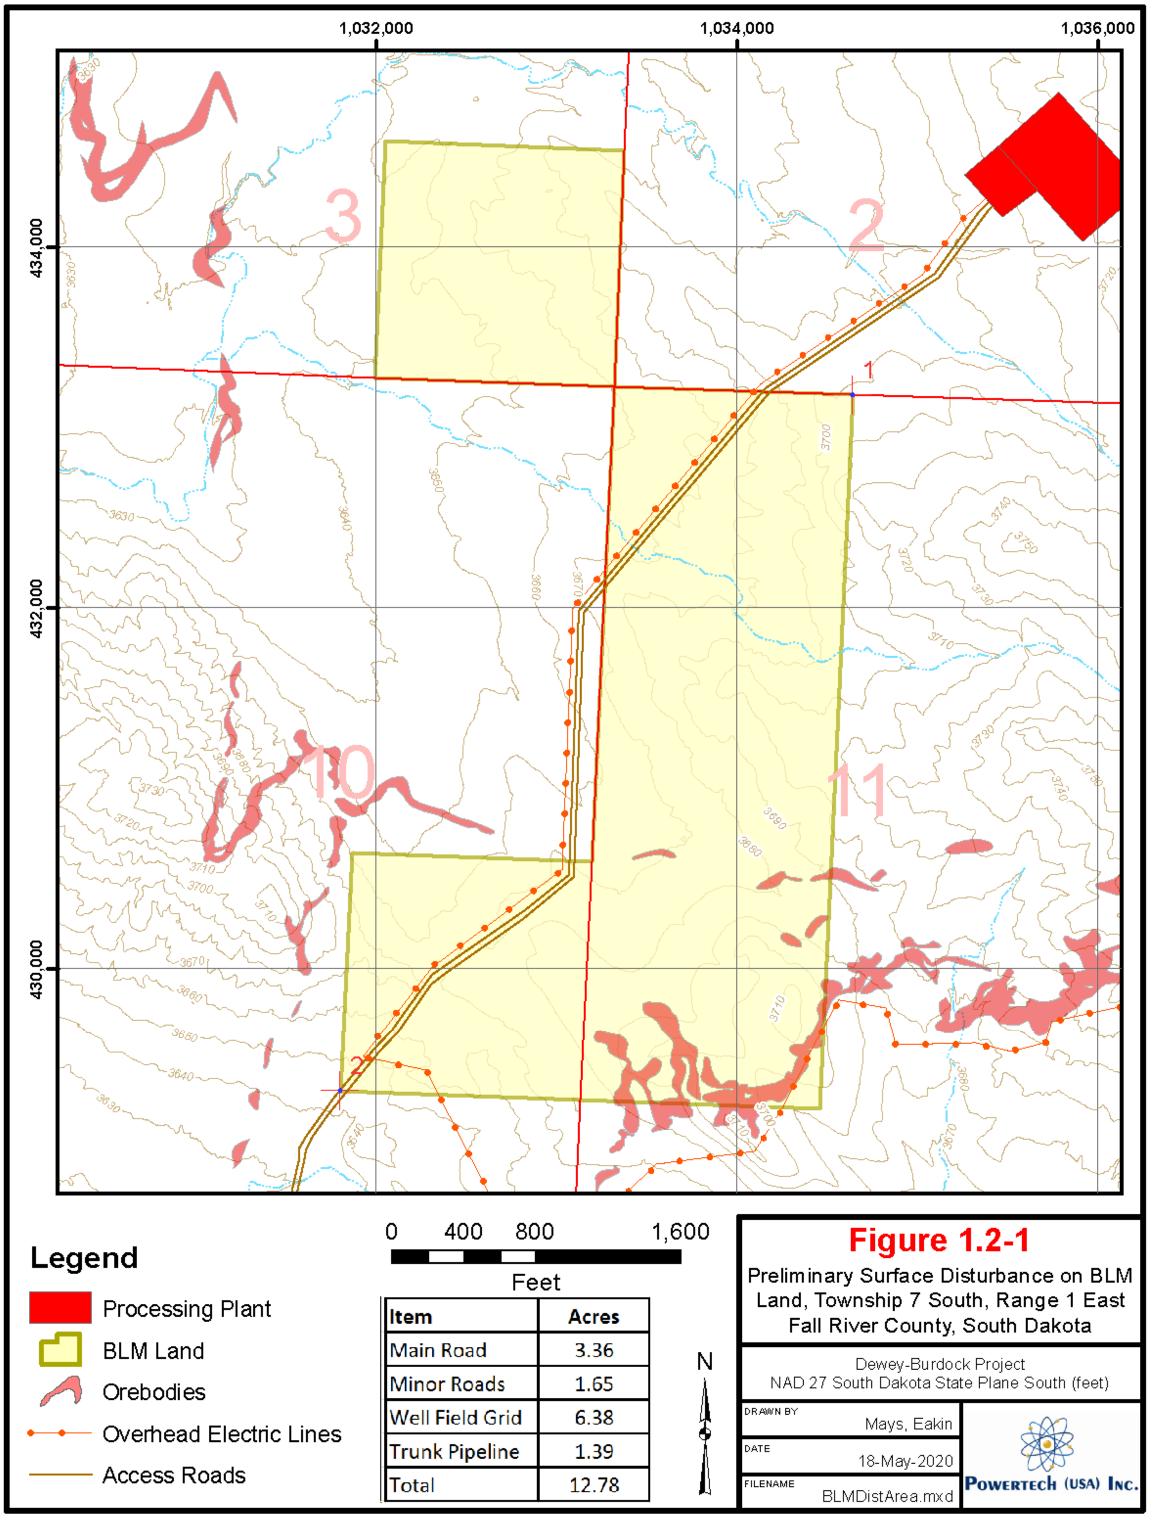
The total surface disturbance acreage described above is slightly less than the value presented to the BLM in Powertech's original submission of the POO, which was 14.2 acres. The new value is the result of a reconfiguration of the main road and a reinterpretation of the uranium ore bodies and their related surface disturbance.

It should be noted that the surface disturbance calculation presented is an estimate based on information known at this time. Following further geologic and hydrogeologic investigations conducted adjacent to BLM managed lands, the applicant will have a better understanding of the exact configuration of operational infrastructure. As this information becomes available, the total BLM surface disturbance for the PA may vary slightly, in which case the BLM will be notified of such changes.

Facilities planned on BLM-administered lands during the initial year of project development include power lines, a portion of the primary access road leading to the central processing plant, associated culverts and drainage ditches, a light-use road (non-constructed, two-track trail), and four perimeter monitor wells. The locations of these planned facilities are shown on Exhibit 1.1-3. No exploration, delineation or production/injection well drilling activities will be conducted on BLM-administered lands during the initial year of project development. If delineation and well field drilling performed later result in less than five (5) acres of surface disturbance, a Notice pursuant to 43 CFR §3809.21 will be filed with BLM and accepted by BLM as complete prior to conducting these surface disturbing activities on BLM administered lands. The information required by 43 CFR §3809.301 will be provided in the Notice.

In addition to the facilities shown on Exhibit 1.1-3, the approximate locations of potential future facilities planned on BLM-administered lands are shown on Exhibit 1.1-4. These potential future facilities include injection/production wells, monitor wells, buried pipelines, fencing, secondary access roads, and light-use roads.

POWERTECH (USA) INC.



Item	Acres
Main Road	3.36
Minor Roads	1.65
Well Field Grid	6.38
Trunk Pipeline	1.39
Total	12.78

Figure 1.2-1 Surface Disturbance on BLM Lands

Proposed processing facilities and support facilities including a central processing plant, a satellite facility, wastewater storage and treatment impoundments, Madison water supply wells, deep disposal wells, and land application center pivot circles will not be located on BLM-administered lands.

No waste rock (mine overburden) or tailings piles will be generated at any time during Powertech's proposed ISR operations at the Dewey-Burdock Project.

Since the proposed project occurs in an area of known cultural resources, Powertech will complete necessary evaluations and assist in the preparation of treatment and/or mitigation plans as prescribed in the Final Programmatic Agreement, dated April 7, 2014 (NRC ADAMS Accession No. ML14066A344), and as required by License Condition 9.8 in Powertech's NRC source and byproduct materials license (NRC ADAMS Accession No. ML14043A392).

Fencing potentially planned for installation on BLM-administered lands during the life of the project consists of approximately 4,500 to 5,500 linear feet of fencing around well fields.

Based on the selection guidance in BLM's Fencing Handbook H-174-1, a wire fence (bottom strand smooth for antelope passage, others barbed) with the following specifications will be used on BLM-administered lands:

- The distance between posts will be between 16.5 and 30 feet.
- The diameter of wooden posts will be between 3 ½ and 4 inches.
- Wooden posts will be buried approximately 2 feet below ground surface.
- Up to three metal posts will be installed between wooden posts and buried to the "bury line" marked on the post.
- H-braces will be 6 to 7 feet wide and constructed using 6-inch diameter wooden posts.
- The bottom, smooth wire will be at least 15 to 16 inches above ground surface for antelope passage.
- The top wire will be no more than 42 inches high to facilitate passage of deer and elk, and the space between the top two wires will be at least 11 to 12 inches to prevent entanglement.

Signage to be attached to the fence will comply with Powertech's NRC License No. SUA-1600, License Condition 9.11, which specifies that signs reading "CAUTION: ANY AREA WITHIN THIS FACILITY MAY CONTAIN RADIOACTIVE MATERIAL" be posted conspicuously at all entrances to the facility. The signs will be posted conspicuously after construction of fencing near the access point for each well field constructed on BLM-administered lands.

Other signage, which may or may not be placed on fencing, includes advisory signs limiting hunting within the vicinity of well fields and processing facilities, and signs at all stockpiled topsoil locations per the requirements of the South Dakota Department of Environment and Natural Resources (SD DENR).

Approximately 3,900 feet of four-wire power line will cross BLM-administered lands as shown on Exhibits 1.1-3 and 1.1-4. It will have a voltage capacity of 14.4/24.9 kV and be constructed of wooden single poles with cross arms. Power poles will be spaced approximately 250 to 275 feet apart. No transformers or switches will be installed on the power lines on BLM-administered lands within the project area.
The power line will be constructed to conform to APLIC recommendations for overhead power line construction by, among other things, providing distances between wires that are adequate to avoid phase-to-phase wingspan contact.

1.3 BLM Claims and Right of Entry

The PAA consists of a combination of private surface, private minerals and federal surface and federal minerals. Surface and mineral acres consisting of 6,120 acres were acquired by landowners through the Homestead Act of May 20, 1862. These lands are controlled by Powertech through active mining leases and purchases. Various landowners acquired 4,220 surface acres through the Stock-Raising Homestead Act of December 29, 1916, whereas the US government retained control all of the minerals under this Act. The 4,220 acres of severed minerals that were retained by the US government under the Stock-Raising Act are controlled by Powertech through unpatented mining claims. In addition, Powertech has located an additional 240 acres (97.1 ha) of unpatented mining claims in accordance with the general Mining Law of 1872 on surface land controlled by the Bureau of Land Management. In conclusion, Powertech controls 10,580 surface and mineral acres either by active mining leases, purchases and unpatented claims. The PAA is located on either side of Dewey Road (previously County Road 6463) and includes portions of Sections 1-5, 10-12, 14 and 15, Township 7 South, Range 1 East and Sections 20, 21, 27, 28, 29 and 30-35, Township 6 South, Range 1 East, Black Hill Meridian. These lands are controlled by Powertech through the staking and acquisition of unpatented Federal Mineral Claims with surface use agreements from the private owners. The 240 acres (97.1 hectares [ha]) of Federal surface are controlled by the BLM and are located in portions of sections 3,10,11 and 12 of Township 7 South Range 1 East. Powertech controls the mineral rights on these lands through unpatented Federal Lode Claims and secures access under the terms of the 1872 mining Law.

The claim serial numbers where disturbance may occur are listed in Table 1.3-1 and are provided in accordance with § 3809.31(2)(d) and § 3809.401 (1). The mineral rights are controlled through unpatented mining claims. Powertech possesses written consent from all the surface owners under active surface use agreements. The surface and minerals under the control of Powertech are illustrated in Exhibit 1.2-1. The proposed permit boundary properties under the control of Powertech (USA) are listed in Table 1.3-2. Land included within the PAA, other than those listed in Table 1.3-1, are private property and are controlled via long-term lease agreements or long-term surface use agreements with the landowners.

POWERTECH (USA) INC.

Section 3.0 - Description of Operations

3.1 Location Description and Maps of the Project Area

The PAA is located approximately 13 miles north-northwest of Edgemont, South Dakota, and straddles the county line between northern Fall River and southern Custer County. The location of the PAA is described in section 1.2, above. Figure 3.1-1 depicts the proposed project location, i.e. the PAA boundary and Exhibit 3.1-1 depicts the Area of Review (AOR) for all operations considered within this application. The PA will consist of well fields comprised of injection, production, and monitoring wells, satellite ion exchange (IX) production facilities, and a central processing plant (CPP) consisting of an elution (resin stripping) system and precipitation, drying and packaging processes to produce a final uranium product (yellowcake). In addition, the PA will include waste management facilities, office buildings and other structures or facilities to house work areas and equipment. During active ISL operations, Powertech (USA) will construct a series of sequentially developed well fields utilizing ISL technologies and processes to produce uranium from identified ore bodies at the Dewey and Burdock sites (Exhibit 3.1-2). The CPP at the Burdock site will perform all processing of uranium loaded IX resin to produce dried yellowcake product, with disposition of the resulting 11e.(2) byproduct material wastes in a manner consistent with NRC and other applicable regulations and guidance. After depletion of the identified ore bodies in operating well fields, Powertech (USA) plans to restore the groundwater in each completed well field consistent with pre-operational or baseline water quality conditions and in accordance with NRC's implementation of 10 CFR Part 40 Appendix A, Criterion 5B(5). After active uranium recovery operations cease, Powertech (USA) intends to complete site decommissioning and decontamination (D&D), including groundwater restoration, with the ultimate goal of releasing the PA site for unrestricted use

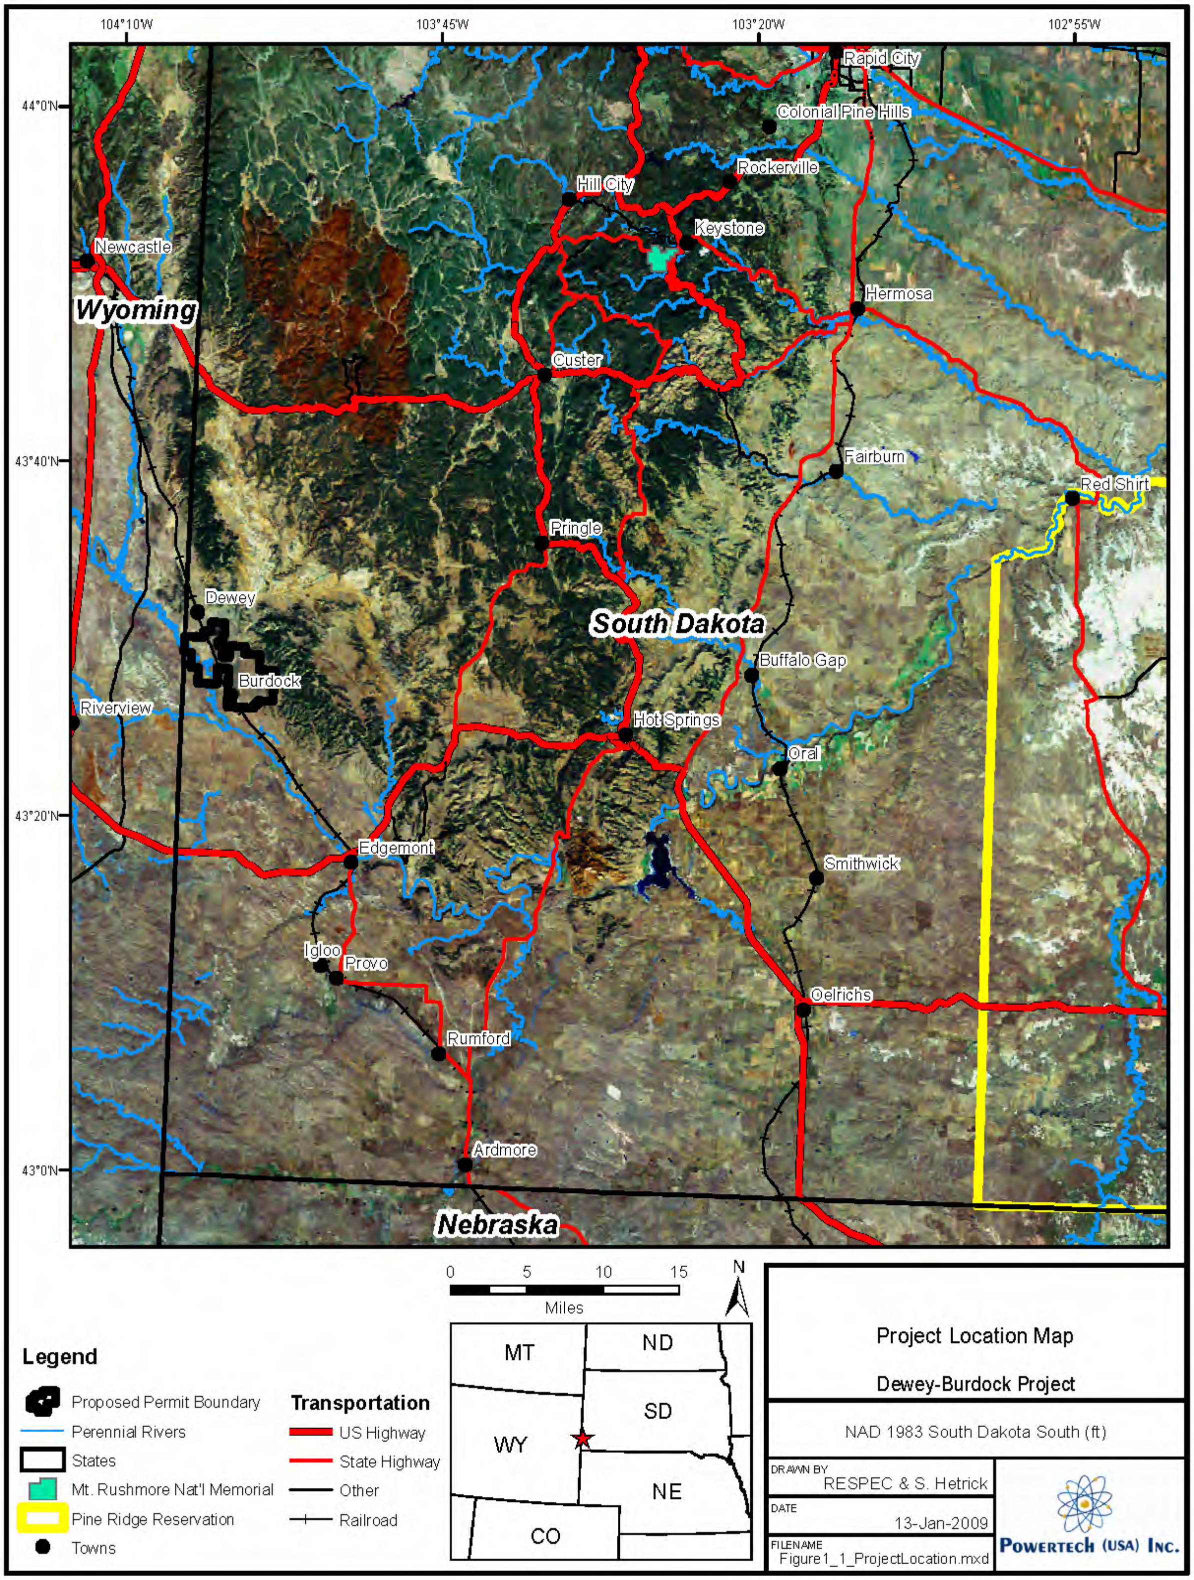

Figure 3.1-1 Proposed Project Location and Site Boundary

3.2 Access Routes

The site can be accessed from the northeast and the west via U.S. Highway 18 to Dewey Road. From the south, the site can be accessed from State Highway 471 to U.S. Highway 18 to Dewey Road. The main access road to the plant facilities and well fields (PAA) is located off Dewey Road in T7S, R1E, and Section 10. This access road joins with several pre-existing roads that traverse through the Burdock Section of the proposed action area (PAA). The Dewey Road also serves as the main access road for the Dewey portions of the PAA. This road joins with several other pre-existing roads. These pre-existing roads within the Burdock and Dewey sections of the PAA will be used to the maximum extent possible in order to minimize surface disturbance. Secondary roads will be built from the existing roads to provide access to other facilities and well fields that are not currently reached from the pre-existing roads.

During the initial year of project development, Powertech plans to construct approximately 3,200 feet of primary access road on BLM-administered lands as shown on Exhibit 1.1-3. The top width of the graveled primary access road will be approximately 28 to 32 feet (two 12-foot lanes and two shoulders). With the drainage ditch dimension included, the total disturbed width of the primary access road will be approximately 45 feet.

Construction of the road will comply with SD DENR requirements as specified in Powertech's large scale mine permit application. Topsoil will be salvaged from the roadbed area prior to construction and placed in designated stockpiles near the primary access road (refer to Section 4 below for additional information on topsoil handling procedures). The road will be surfaced with gravel and include a centerline crown of approximately 2%.

The use of water bars is not planned for cross drainage. Road surfacing, ditching and culverts will be designed to provide adequate drainage and cross drainage. Culverts will be sized and constructed in accordance with SD DENR requirements as specified in Powertech's large scale mine permit application to avoid plugging and collapsing and to minimize erosion at the culvert inlets and outlets. Exhibit 1.1-3 depicts the approximate location of anticipated culverts along the primary access road on BLM-administered lands.

Sediment control for the primary access road will include seeding side slopes and disturbed areas with the seed mixture approved by SD DENR and implementing erosion control measures such as a silt fence and check dams. As a condition of the large scale mine permit, Powertech will be required to submit a final sediment and erosion control plan to SD DENR prior to commencing construction.

In addition to the primary access road, Powertech plans to install approximately 1,300 feet of light-use road on BLM-administered lands during the initial year of project development. The light-use road will be a non-constructed, un-surfaced, two-track trail that is approximately 8 feet wide. Its primary use will be to access the perimeter monitor wells planned on BLM-administered lands using light-duty pickup trucks or other passenger vehicles.

Currently, approximately 8,000 feet of two-track roads exist on BLM-administered lands within the project boundary. To the extent practicable, these existing two-track roads will be used for light-use roads or upgraded to serve as primary access or secondary access roads.

Potential future development on BLM-administered lands may include the addition of approximately 3,000 feet of secondary access roads and 6,800 feet of light-use roads as shown on Exhibit 1.1-4. Secondary access road construction, topsoil handling, drainage, and surfacing will be the same as the primary access road, except that the top width will be narrower (typically 15 to 24 feet) due to the lower traffic demands of the road compared to the primary access road. Secondary access road culverts will be designed in accordance with SD DENR large scale mine permit requirements.

Maintenance of all primary and secondary access roads will be performed routinely and as needed and will include grading, gravel replacement and watering for dust control. Light-use roads will be maintained as necessary and travel on light-use roads will be restricted during adverse weather conditions to minimize erosion.

Powertech plans to apply water to control dust on primary and secondary access roads, including those located on lands administered by BLM. Use of water for dust suppression was incorporated into the project fugitive dust modeling, which was completed in cooperation with BLM, presented to NRC as part of Powertech's source and byproduct materials license application (ADAMS Accession Nos. ML13196A061, ML13196A097 and ML13196A118), and addressed in the Final Supplemental Environmental Impact Statement (FSEIS, ADAMS Accession Nos. ML14024A477 and ML14024A478).

The locations of planned primary and secondary access roads on BLM-administered lands where water may be applied are shown on Exhibits 1.1-3 and 1.1-4.

Powertech does not plan to use other dust abatement agents such as magnesium chloride within the project area.

Any additional routes constructed by Powertech (USA) on BLM managed lands will be planned for only the minimum width needed for operations and shall follow natural contours, where practicable, to minimize cut and fill. If access routes require cuts on the inside edge in excess of 3 feet on public lands, Powertech (USA) will consult with the authorized officer of BLM concerning the methods and location that would create the least amount of degradation (§ 3809.415(6)(b)). Exhibit 3.1-1 displays the potential location of facilities for the proposed project. Also displayed on this figure are the first two mine unit locations, wells within the proposed permit boundary and within one mile surrounding the project area, utilities, residences, and roads.

3.3 Preliminary and Conceptual Designs for Facilities and Cross Sections for Mine Areas/Technology and Practices

The ISL process involves the oxidation and solubilization of uranium from its reduced state using leach fluid (lixiviant). The leach fluid consists of native ground water with an oxidant, such as gaseous oxygen, added to oxidize the uranium to a soluble valence and gaseous carbon dioxide to complex and solubilize the uranium ion causing it to go into solution in the leach fluid flowing through the ore zone. At the well fields, Powertech (USA) will add gaseous oxygen and gaseous carbon dioxide to the recirculated native ground water from the ore zone aquifer. Once solubilized, the uranium bearing ground water will be pumped by submersible pumps via well field production wells to the surface where the uranium is ion exchanged onto ion exchange (IX) resin. After the uranium is removed, the groundwater will be refortified with O_2 and CO_2 and reinjected via well field injection wells. When the IX resin is loaded with uranium, the loaded resin is moved to an IX elution (stripping) column at the CPP where the uranium is eluted (stripped) off the resin by a salt water solution. The resulting barren (stripped) resin is then recycled to recover more uranium. The salt water eluate solution is pumped to a precipitation process where the uranium is precipitated as a yellow solid uranium oxide. The precipitated uranium oxide is then filtered, washed, dried and packaged in sealed containers for shipment to a conversion plant for further processing.

Typically, an ISL well field consists of a set of contiguous geometric shaped patterns of injection and production wells. Powertech (USA) generally will utilize square or rectangular patterns, and sometimes hexagons or triangles to cover the economically recoverable portions of the uranium orebody. This provides for uniform distribution of leach fluid (lixiviant) to efficiently contact the uranium ore. The injection wells will be located at the corners of the geometric patterns and the production wells will be in the center. The lixiviant is pumped into the injection wells and is drawn to the adjacent production well due to the hydraulic gradient formed from the pressure sink created by the pumping well. The production rate is estimated to be between 20-30 gallons per minute (gpm) from each production well. Flow into each of the injection wells is based on the number and configuration of adjacent production wells. The overall injection rate is set to balance flow from the injection wells to the production wells such that slightly more water is produced from each pattern than injected to maintain control of the flow regime. For the entire well field, Powertech (USA) will withdraw 0.5 to 3 percent more ground water than is reinjected to maintain a cone of depression as a pressure sink in the well field. This causes flow of outside baseline quality ground water into the well field and prevents the flow of leach fluid to the monitor well ring surrounding the orebody. The excess produced water (bleed) forces native ground water to continually flow toward the center of the production zone. This bleed also allows Powertech (USA) to control and limit the increase in total dissolved solids (TDS) from the oxidation of reduced chemical species in the ore zone. Over-pumping the production wells prevents the loss of the lixiviant outside of the intended production area and protects ground water outside of the monitor well ring.

Within the SF, the pregnant lixiviant flows through IX columns, where the uranium is transferred to resin. The resin will be trucked or piped to the CPP for further processing into final uranium product (yellowcake).

The barren lixiviant is re-fortified with oxygen and carbon dioxide and re-circulated through the orebody to continue the leaching process. A detailed description of the proposed ISL process is available on (Agency Document Access Management System (ADAMS) http://www.nrc.gov/reading-rm/adams.html in Section 3 of the Technical Report submitted to NRC.

3.3.1 Operating Plans, Design Throughput, and Production

The Proposed Action will utilize uranium ISL production facilities at both the Dewey and Burdock sites with a satellite facility (SF) located at Dewey and a CPP located at the Burdock site see Exhibit 3.1-1. The IX process and well fields are designed for a nominal flow rate of 2000 gpm at each site. Total production from both sites is expected to produce approximately 1,000,000 pounds of U_3O_8 per year.

Refer to Section 7.1 Regional Structure and Stratigraphy and 7.2 Site Structure and Stratigraphy for review of regional and site cross sections.

3.4 Water Management

3.4.1 Operational Water Use

During ISL operations (including both production and restoration) nominal bleed rates of .5-1 percent are expected to be maintained over the life of the project. Instantaneous rates may vary in the range of 0.5 percent to 3 percent for short durations, from a few days to a few months. All effluent systems for treating bleed streams are designed for continuous operation at the maximum bleed rate of 3 percent. However, over the life of the project, a reasonable estimate of .5-1 percent bleed is believed appropriate and sufficient to maintain the cone of depression.

It is anticipated that no more than two well fields, typically one at the Dewey site and one at the Burdock site, will be in production at any given time, with another two in restoration. Restoration will begin as soon as each well field has been depleted of uranium, beginning approximately one to two years after the start of operations. When one well field is depleted, it will be reclaimed at the same time production continues in another well field along the ore trend. This information is repeated in section 5.7.6.9.1 with respect to potential impacts from conducting operations and restoration of groundwater simultaneously.

3.4.1.1 Water Requirements for the Proposed Action Facilities

Additional water requirements for dust control and the CPP processing are estimated to be a maximum of 65 gpm. It is expected that most of this water will be derived from a water supply well to be completed in the Madison formation.

3.4.1.2 Water Usage with Reverse Osmosis and without Reverse Osmosis

Net water use for production operations (as well field bleed) will be in the range 20-120 gpm from the Inyan Kara, with both the Dewey and the Burdock production sites consuming between 10 and 60 gpm as well field bleed. During restoration operations, production of water will be greater from the Inyan Kara. However, water consumed will be replaced with better quality water from the Madison well(s). Therefore, net withdrawal from the Inyan Kara formation will also remain at the range of 0.5 to 3 percent of total restoration flow due to treatment of the water with reverse osmosis (RO) (Table 3.4-1). It is expected that the restoration activities will also be split between the two sites. Net withdrawal during these restoration operations (as well field bleed) is expected to be a total of 2.5 to 15 gpm from the Inyan Kara. At each site, Dewey and Burdock, 1.25 to 7.5 gpm will be the net withdrawal during restoration operations. Net water usage from the Madison using an RO unit to restore groundwater following production, approximately 167 gpm of the 500 gpm (without RO utilization; Table 3.4-2), will need to be made up with Madison aquifer water.

The actual flow rates of water leaving the Inyan Kara formation during restoration operations is expected to be in the range of 150-500 gpm. Nearly all of this water will be “made-up” by injection of water from two sources, the Madison and Inyan Kara Formations.

Madison Formation

The Madison Limestone Formation occurs at approximate depths throughout the project area (2800 – 3200 ft deep). Based on the regional development potential of the aquifer as a source of good quality water, Powertech proposes the installation of a well, or wells, to produce make-up water from the Madison to be used to supplement and replace produced water from the Inyan Kara for both operational bleed and restoration withdrawal. Depending on the final process used, Powertech (USA) may need to produce up to 500 gpm from the Madison aquifer.

In the case of land application disposal of water during restoration, 500 gpm of make-up water will be required from the Madison aquifer. With the RO process used for treating well field bleed streams, permeate will be reinjected and will substantially lower the requirement for makeup water from the Madison; such use of RO typically reduces make-up water requirements to approximately 1/3 (or approximately 167gpm) of the water that would be required without RO (Table 3.4-2).

The actual net difference between fluid produced and fluid injected must be maintained at a rate equivalent to the 0.5-3 percent bleed rates described above. As described above, it is very likely that the Madison aquifer can provide a source of water at the desired rate and quality sufficient for the needs of Powertech (USA) to ensure timely and successful ISL restoration goals.

Inyan Kara Formation

Make-up water is derived from the Inyan Kara formation by withdrawing more bleed thus drawing in more water from the Inyan Kara outside the monitor well ring. Also make up water may be provided by withdrawing from wells that are located far enough from operating well fields so as to not affect the cone of depression within the operating well fields.

3.5 Effluent Control Measures

Surface Water Control

All of the Dewey-Burdock facilities are located outside of the FEMA 100-year flood plain. As part of the wastewater management plan, there may be periodic releases of water from storage ponds for the beneficial use of crop irrigation.

For well fields and non-CPP/SF areas, storm water management will include general grading of roads and building pads to promote positive drainage toward existing water courses. Best management practices (BMPs) for sediment control during construction and operations will be provided until vegetative cover on disturbed ground has been reestablished. Such practices will include, but not be limited to, use of silt fences and hay bales downstream of disturbed areas, and as necessary, long-term erosion protection using stream channel armoring such as rip rap, gabions, and/or geotextiles.

For the CPP/SF areas, and contiguous operational areas, excess runoff above pre-existing conditions will be temporarily detained to assure that peak runoff flow is no greater than peak flow prior to construction. BMPs will include construction of bermed parking lots and routing flow into storm water detention areas with controlled outlet structures. Sediment control during construction will be accomplished using similar BMPs.

Surface water/groundwater interactions and potential impacts to these media from site activities are discussed in Section 7 of this application.

Gaseous and Airborne Particulates

Powertech (USA) will conduct an airborne radiation monitoring program at the Dewey-Burdock facility which is consistent with the recommendations contained in RG 8.30 and will consist of monitoring radon decay products as well as airborne particulate monitoring. Also, Powertech (USA) will conduct an airborne effluent and environmental monitoring program during construction and operations consistent with recommendations in NRC Regulatory Guide 4.14 “Radiological Effluent and Environmental Monitoring at Uranium Mills” (RG 4.14).

This section describes the expected radionuclide airborne emissions from the Dewey-Burdock uranium recovery facilities. Airborne emissions are categorized in two subsections, radon and radionuclide particulates. Potential sources of emissions and a basic description of monitoring for worker protection are based on the design of the process as well as the emissions control systems that will be employed to maintain radionuclide effluents well below regulatory limits and “as low as reasonably achievable” (ALARA).

Radon

According to NRC’s RG 8.30, measurement of radon decay products is the superior method for determining worker dose than radon measurements. Consequently, Powertech (USA) will measure radon decay products in the facility. Working level (WL) measurements for radon decay products will be made on a monthly basis in areas where radon decay product concentrations are likely to exceed 0.03 WL as described in RG 8.30. The time, date, and state of operation of the pertinent equipment in the vicinity of the measurements will be recorded.

The primary radioactive airborne effluent at the Dewey-Burdock ISL facility will be radon-222 gas. Radon-222 is dissolved in the pregnant lixiviant that comes from the well field into the IX facilities for separation of uranium. At the locations where the lixiviant solution is first exposed to atmospheric pressure and ambient temperatures, radon gas will evolve. These are primary release points and include the IX vessels where uranium ion exchange loading occurs and the shaker screens where sediment is separated from ion exchange resin, prior to elution (NMA 2007, Brown 1982, 2007, 2008). The IX vessels normally operate as sealed, pressurized vessels, such that radon releases only occur during resin transfer operations. Dedicated local exhaust at the IX vessels and shaker screens will be directed to a manifold that is vented to the atmosphere outside the building via an induced draft fan. Exhausting radon-222 gas to the atmosphere outside the plant minimizes opportunity for in-growth of radon particulate daughter products (progeny) in occupied work areas and therefore minimizes employee airborne radiological exposure. Small amounts of radon-222 may be released from the well field, solution spills, filter changes, 11e (2) by-product impoundment areas, reverse osmosis (RO) system operation during groundwater restoration, and maintenance activities. These secondary and/or infrequent additional releases would be quite small relative to radon dissolved in the pregnant lixiviant returning from underground. Radon releases associated with these secondary release points have been shown to be minor components of the overall facility radon-222 source term (NMA 2007, Marple and Dziuk 1982, Brown 1980, 2007, 2008). An operational monitoring program will be established to measure radionuclide particulates and radon-222 in the atmosphere outside the buildings and other specified locations within the PAA.

The general heating, ventilating and air conditioning (HVAC) system in the plant will further reduce employee exposure by removing radon from plant air and will be exhausted through a separate ventilation system. This system will be connected via ductwork and manifolds to the eluant and precipitation tanks. Potential release points as well as general air in the plant will be routinely sampled for radon daughters to assure that concentration levels of radon and progeny are maintained ALARA. Sampling and monitoring methods specific for radon progeny will be used (NRC 2002a). Results of monitoring obtained during initial plant operation will be used to adjust monitoring programs (location and frequency), ventilation and/or other effluent control equipment as may be necessary.

Redundant exhaust fans will direct collected gases to discharge piping that will exhaust fumes to the outside atmosphere. Redundancy of fans will minimize employee exposures should any single fan fail. Discharge points will be located away from building ventilation intakes to prevent introducing exhausted radon back into the facility (NRC 2002b). Airflow through any openings in the vessels will be from the process area into the vessel and then into the ventilation systems, maintaining negative flow into the vessel and controlling any releases. (Note that the lixiviant circuit through IX will be a closed system; atmospheric conditions will initially be encountered during resin transfer at the shaker screens.) Tank ventilation of this type has been successfully utilized at other ISL facilities and proven to be an effective method for minimizing employee exposure. (Brown 1982, 2007, 2008)

The general building ventilation system will be designed to maintain air flow from the least likely airborne release locations to the most likely potential release locations prior to external exhaust. Ventilation systems will exhaust outside the buildings and draw in fresh air. During favorable weather conditions, open doorways and convection vents in the roof will provide supplemental work area ventilation.

Radionuclide Particulates

Continuously operating air samplers will be analyzed quarterly for natural uranium, thorium-230, radium-226, and lead-210. Passive track-etch detectors will be deployed at each station for monitoring radon-222 on a quarterly basis. The maximum lower limits of detection (LLDs) for the analyses will be consistent with the recommendations of NRC's RG 4.14. Additionally, effluents from the yellowcake dryer and packaging vent system will be sampled quarterly. The grab samples will be isokinetic in nature and will be analyzed for natural uranium, thorium-230, radium-226, and lead-210. The maximum LLDs for the analyses will be consistent with recommendations of NRC's RG 4.14.

Since there will be no ore grinding at the facility, monitoring of airborne uranium ore dust will not be necessary. However, airborne yellowcake will be monitored at the facility. The facility will be drying yellowcake under low temperatures between 200 and 400°F (93.3-204.4 °C). According to the footnotes of 10 CFR 20 Appendix B, yellowcake dried under low temperature should be considered soluble. Weekly 30 minute grab samples (low volume breathing zone samples) will be taken in airborne radioactivity areas. Breathing zone samples provide a better estimate of airborne particulate concentrations to which workers are exposed, resulting in a more representative estimate of actual intakes. The sensitivity of this method shall be at least 1 x 10-11 µCi / mL. Breathing zone samples will be taken during non-routine operations with potential for a worker to receive exposure to airborne yellowcake above 1 x 10-10 µCi / mL.

Precipitation and Dewatering

Potential radiological air particulate effluents are generated primarily from dried uranium concentrate in the yellowcake drying and processing areas. Following precipitation of uranium from solution, the uranium concentrate is fed to a gravity thickener. The gravity-thickened yellowcake slurry will be pumped into a plate and frame filter press for dewatering. At this point the product contains approximately 60 percent solids content. Dewatered yellowcake drops from the filter press into a live bottom hopper with a screw auger to move the pressed yellowcake slurry to a sump where a progressing-cavity positive displacement pump transfers the yellowcake to the dryers. Although minor spills can occur during the thickening and dewatering process, they would be cleaned up quickly and the area would subsequently be surveyed to minimize any potential airborne source.

Yellowcake Drying and Packaging

Yellowcake drying will be undertaken with a vacuum dryer.

The vacuum drying system is proven technology, which is being used successfully at several ISL facilities (NMA 2007). The off gas treatment system of the vacuum dryers includes a baghouse, condenser, vacuum pump, and packaging hood. The yellowcake will be dried at the standard operating drying range of 200-400 °F (93.3-204.4 °C) in the rotary vacuum drying process. The off gases generated during the drying cycle are filtered through a baghouse, which is located on the top of the dryer, to remove particles down to approximately 1 micron in size. The gases are then cooled and scrubbed in a surface condenser to further remove the smaller size fraction particulates and the water vapor during the drying process. Two rotary vacuum dryers will be located in a separate building attached to the CPP. This attached building will contain the dryers, the bag houses on the dryers, and a condenser scrubber and vacuum pump system for each dryer. The dryers will be heated with a heat transfer fluid (HTF) that circulates through the shell and the rotating central shaft. The heat transfer fluid will be heated by two natural gas or propane-fired HTF heaters, each provided with HTF pumps for circulating the HTF through the shell and central shaft of the dryer. The HTF heaters and pumps will be in a separate structure attached to the back of the dryer building. The water-sealed vacuum pumps will provide the vacuum source while the dryer is being loaded and while the yellowcake is unloaded into drums.

The vacuum dryers are steel vessels heated externally as described above and fitted with rotating plows to stir the yellowcake. The chamber will have a top port for loading the wet yellowcake and a bottom port for unloading the dry powder. A third port will be provided for venting through the baghouse during the drying procedure. The baghouse and vapor filtration unit will be mounted directly above the drying chamber so that any dry solids collected on the bag filter surfaces can be batch discharged back to the drying chamber. The baghouse will be heated to prevent condensation of water vapor during the drying cycle. It will be kept under negative pressure by the vacuum system.

The condenser will be located downstream of the baghouse and will be water cooled. It will be used to remove the water vapor from the non-condensable gases emanating from the drying chamber. The gases are moved through the condenser by the vacuum system. Dust passing through the bag filters is wetted and entrained in the condensing moisture within this unit. The vacuum pump will be rotary water sealed providing negative pressure on the entire system during the drying cycle. It will also be used to provide negative pressure during transfer of the dry powder from the drying chamber to 55-gallon steel drums. The water seal of the rotary vacuum pump captures entrained particulate matter remaining in the gas streams.

The packaging system will be operated on a batch basis. When the yellowcake is dried sufficiently, it will be discharged from the drying chamber through a bottom port into 55-gallon steel drums. A level gauge, a weigh scale, or other suitable device will be used to determine when a drum is full. Particulate capture will be provided by a sealed hood that fits on the top of the drum, which will be vented through a sock filter to the condenser and the vacuum pump system when the powder is being transferred.

Atmospheric Discharges from the Yellowcake Drying and Packaging System
The yellowcake drying and packaging area will be serviced by a dedicated ventilation system. The vacuum pump is the only piece of equipment in the area that discharges to the atmosphere. The vacuum pump is a rotary water sealed unit that provides a negative pressure on the entire system during the drying cycle. It is also used to provide ventilation during transfer of the dry powder from the drying chamber to 55-gallon drums. The water seal of the rotary vacuum pump captures entrained particulate matter remaining in the gas streams, which is recycled back to the process. This point of discharge will be routinely monitored via filter collection and radiochemical analysis for Natural U, Th 230, Ra 226 and Pb 210 to ensure radionuclide effluent releases are maintained ALARA. The water that is collected from the condenser will be recycled to the precipitation circuit, eluant makeup, or disposed with other process water. General plant air will be monitored routinely for airborne radionuclides.

The system will be instrumented sufficiently to operate automatically and to shut itself down for malfunctions such as heating or vacuum system failures. The system will alarm if there is an indication that the emission control system is not performing within operating specifications. If the system is alarmed due to the emission control system, the operator will follow standard operating procedures to recover from the alarm condition, and the dryer will not be unloaded or reloaded until the emission control system is returned to normal service.

To ensure that the emission control system is performing within specified operating conditions, instrumentation will be installed that signal an audible alarm if the air pressure (i.e. vacuum level) rises above specified levels, and the operation of this system is routinely monitored during dryer operations. The operator will perform and document inspections of the differential pressure or vacuum every four (4) hours. Additionally, the air pressure differential gauges for other emission control equipment is observed and documented at least once per shift during dryer operations.

Other Airborne Emissions
Other emissions to the air are possible from limited vehicular traffic (exhaust and dust). There will not be any significant combustion related emissions from the process facility as commercial electrical power is available to the site.

Liquid Effluent Sources
The primary source of liquid waste is the operation of the IX process which generates production bleed. This bleed will either be sent to a deep disposal well or will be treated with barium chloride to precipitate radium and then to a radium settling pond to settle and remove the radium. From there, the water suitable for discharge will be used to irrigate alfalfa or other crops suitable for animal feed within the permit area using center-pivot sprinklers. Other sources of liquid waste from the CPP include laboratory chemicals, laundry water, plant wash down water and the waste brine streams from the elution and precipitation circuits; however, these liquid waste streams make up a much smaller portion of the total liquid waste stream at the Dewey-Burdock facility. These wastes will be collected, treated, and discharged to the deep disposal well.

Well Field Development Effluent
During well development or redevelopment, water will be collected, treated and the waste will be disposed of via a deep disposal well or treatment and land application. Water from injection lixiviant or recovery fluids recovered from areas where a liquid release has occurred from a pipeline or well will be placed into the wastewater disposal system for either deep well disposal or treatment and land application.

Storm Water Runoff
DENR is responsible for administering the stormwater management program that is closely modeled after the federal National Pollution Discharge Elimination System (NPDES) program. Facility drainage will be designed to route storm water runoff either away from or around the plant, ancillary buildings and parking areas, and chemical storage. The design of the project facilities, combined with engineering and

procedural controls contained in a Best Management Practices (BMP) Plan, will ensure that storm water runoff is not a potential source of pollution.

3.6 Quality Assurance Plans

Powertech (USA) will establish a quality assurance program at the facility consistent with the recommendations contained in NRC Regulatory Guide 4.15 “Quality Assurance for Radiological Monitoring Programs (Inception through Normal Operations to License Termination) - Effluent Streams and the Environment” (RG 4.15). The purpose of the program is to ensure that all radiological and nonradiological measurements that support the radiological monitoring program are reasonably valid and of a defined quality. These programs are needed (1) to identify deficiencies in the sampling and measurement processes and report them to those responsible for these operations so that licensees may take corrective action and (2) to obtain some measure of confidence in the results of the monitoring programs to assure the regulatory agencies and the public that the results are valid.

The quality assurance program will contain the following RG 4.15 elements:

- The organizational structure, responsibilities, and qualifications of both the management and the operational personnel.
- Specification and qualifications of personnel.
- The SOPs used in the monitoring programs.
- The records of samples, from collection to shipping to analysis.
- The records of quality control of the sample analyses, including results of quality control blanks, duplicates, and cross-checks performed by other laboratories.
- The calibration and operation of equipment used in obtaining samples, measuring radiation, etc.
- Data verification and validation procedures.
- The data and calculations used to determine concentrations of radioactive materials, radiation doses due to occupational exposure, etc.

Quality assurance procedures, as described in RG 4.14 will be defined for the following programs:

- External Monitoring Program
- Airborne Radiation Monitoring Program
- Contamination Control Program
- Airborne Effluent and Environmental Monitoring Program
- Management Control Program

Additionally, quality assurance recommendations contained in RG 4.14 and RG 8.22 will be incorporated in the environmental monitoring and bioassay programs, respectively. In general, the quality control requirements for a specific activity will be incorporated into the SOP for that activity.

The quality assurance program will be audited periodically. The audits will be conducted by individuals qualified in radiochemistry and monitoring techniques. However, the auditors will not have direct responsibilities in the areas being audited. An example of an appropriate auditor is a consultant. The results of the audits will be documented and made available to members of management with authority to enact any changes needed (i.e. RSO, Mine Manager, etc.).

3.7 Spill Contingency Plans

Procedures to address and respond to potential spills will be the responsibility of the radiation safety department; engineers and operations supervisors will assist in development of procedures. The SERP will review the procedure for effectiveness. Procedures developed will implement appropriate protocol to handle potential spills of radioactive materials. Nine responsibilities comprise basic activities:

- Resources and manpower assigned.
- Material and Inventory.
- Identification of potential spill sources.
- Spill reporting and visual inspection program established.
- Review of past spill incidents.
- Coordination among all departments for containment of spills.
- Emergency response protocol established.
- Program implementation, review and updating.
- New construction and changes in process relative to prevention and control of spills will be reviewed.

There are two types of spills that may result from an in situ operation:

<u>Surface Releases</u>
Potential surface releases may be the result of a tank failure, ruptured pipe, or transportation incident.

Failure of a process vessel will be contained within the CPP via berms and directed into a sump (equipped with a level alarm) that will allow the solution to be transported to appropriate tank or disposal system.

Piping system leaks is the most common source of surface releases that occur at an in situ facility. Generally these spills are small due to engineering controls set up to detect changes in pressure within the piping systems. Operators are alerted via an alarm system when pressure changes occur. Well field piping systems are constructed of PVC or high density polyethylene (HDPE) materials with butt welded joints or the equivalent. All pipelines will be pressure tested at operating pressures before put online. No additional stress is placed on the buried pipes so it is improbable a break would occur. The underground portions of the pipes are protected from vehicles and exposed pipes only occur at the wellheads and header houses. Trunkline flows and wellhead pressures will be monitored for process control. Spill response is specifically addressed in the Emergency Response Procedures (Energy Metals Corporation, U.S, 2007).

Spills related to transportation will be addressed in the Emergency Response Action Plan. Specific actions involving response to a radioactive materials shipment will include instructions for appropriate packaging, documentation, driver emergency and accident response procedures and cleanup and recovery protocol. The water contained in the piping and potentially in spills contains only very low concentrations of uranium, generally less than 100 parts per million, consequently radiation dose to a clean-up crew would be minimal. If there is a spill, it will be easily detected and removed to a licensed low-level radioactivity disposal site.

<u>Subsurface Releases</u>
Potential subsurface releases such as a well excursion may result in the migration of process fluids.

Monitoring wells will be set up around the well field for detection of any leach fluids that may potentially migrate away from the production zone due to an imbalance in well field pressure. The monitoring well detection system is a proven method historically among ISL operations. Powertech (USA) proposes to locate a ring of monitoring wells no farther than 400 feet from the well field. These monitoring wells will be screened in the same zone as the production well. There will be additional wells monitoring the aquifers above and potentially below the ore-bearing aquifer. Sampling of monitoring wells will occur on a weekly or bi-weekly basis. Recovery and monitoring work in conjunction, as a coordinated effluent control system, and has proven effective in early detection of recovery fluids for a number of reasons:

- Close proximity of monitoring wells to well field
- Low flow of production wells
- Cone of depression created from production bleed

The overall effect of the system makes non-detection highly unlikely.

Effluent controls for preventing migration of recovery solutions to overlying and underlying aquifers consist of:

- Plugging and Abandonment of all exploration holes.
- Conducting Mechanical Integrity Tests (MITs) on each well before it is put on line.
- Sampling the monitoring wells located within the overlying and underlying aquifers on a frequent schedule.

These controls work together to prevent and detect production fluid migration. Plugging exploration holes prevents connection of the ore-bearing aquifer to overlying and underlying aquifers. The EPA UIC requirement of MITs assures proper well construction and is the first line of defense for maintaining appropriate pressure without leakage. Sampling the monitor wells will enable early detection of any production solutions should an excursion occur.

Sediment or erosion of existing soils has the potential to lead to a release of undesirable elements in addition to the aforementioned spills. The greatest likely hood of this type of release may occur during the construction phase of the project. Two types of Best Management Practices (BMPs) will be employed to minimize the effects of runoff during precipitation events. One type is erosion prevention practices and the second type is sediment control practices.

Erosion Prevention Practices utilize ground covers that prevent different types of erosion from occurring. Ground covers include but are not limited to:

- Vegetation
- Riprap
- Mulch
- Blankets

Sediment control practices prevent soil particles that are being carried in storm water from leaving the site. These types of controls may consist of:

- Silt fence
- Sediment traps
- Sediment basins
- Vegetative cover

Leaving as much of the vegetation in place for as much of the construction period as possible will reduce the potential for a precipitation event to cause significant erosion and soil loss on-site. Utilizing erosion prevention and sediment controls in combination will prevent sediment loss during a major precipitation event. In addition to the above mentioned controls, engineering design and administrative controls will also minimize and control erosion and runoff. Should a pipeline failure coincide with a precipitation event, there is potential for a release. Relative soil saturation beneath the leak area would be a determining factor to what extent the material would be able to be absorbed. In any event with rapid detection and quick spill response a pipeline failure and migration of solutions due to runoff would be minimal.

Wells That May Require Corrective Action

For decades, it has been common practice in the area to allow free-flowing wells to continually discharge, largely to prevent freezing during winter. The attached map shows artesian wells within the AOR that will be monitored to determine if corrective action will be needed (Figure 3.7-1). This determination will be made during well field design phase.

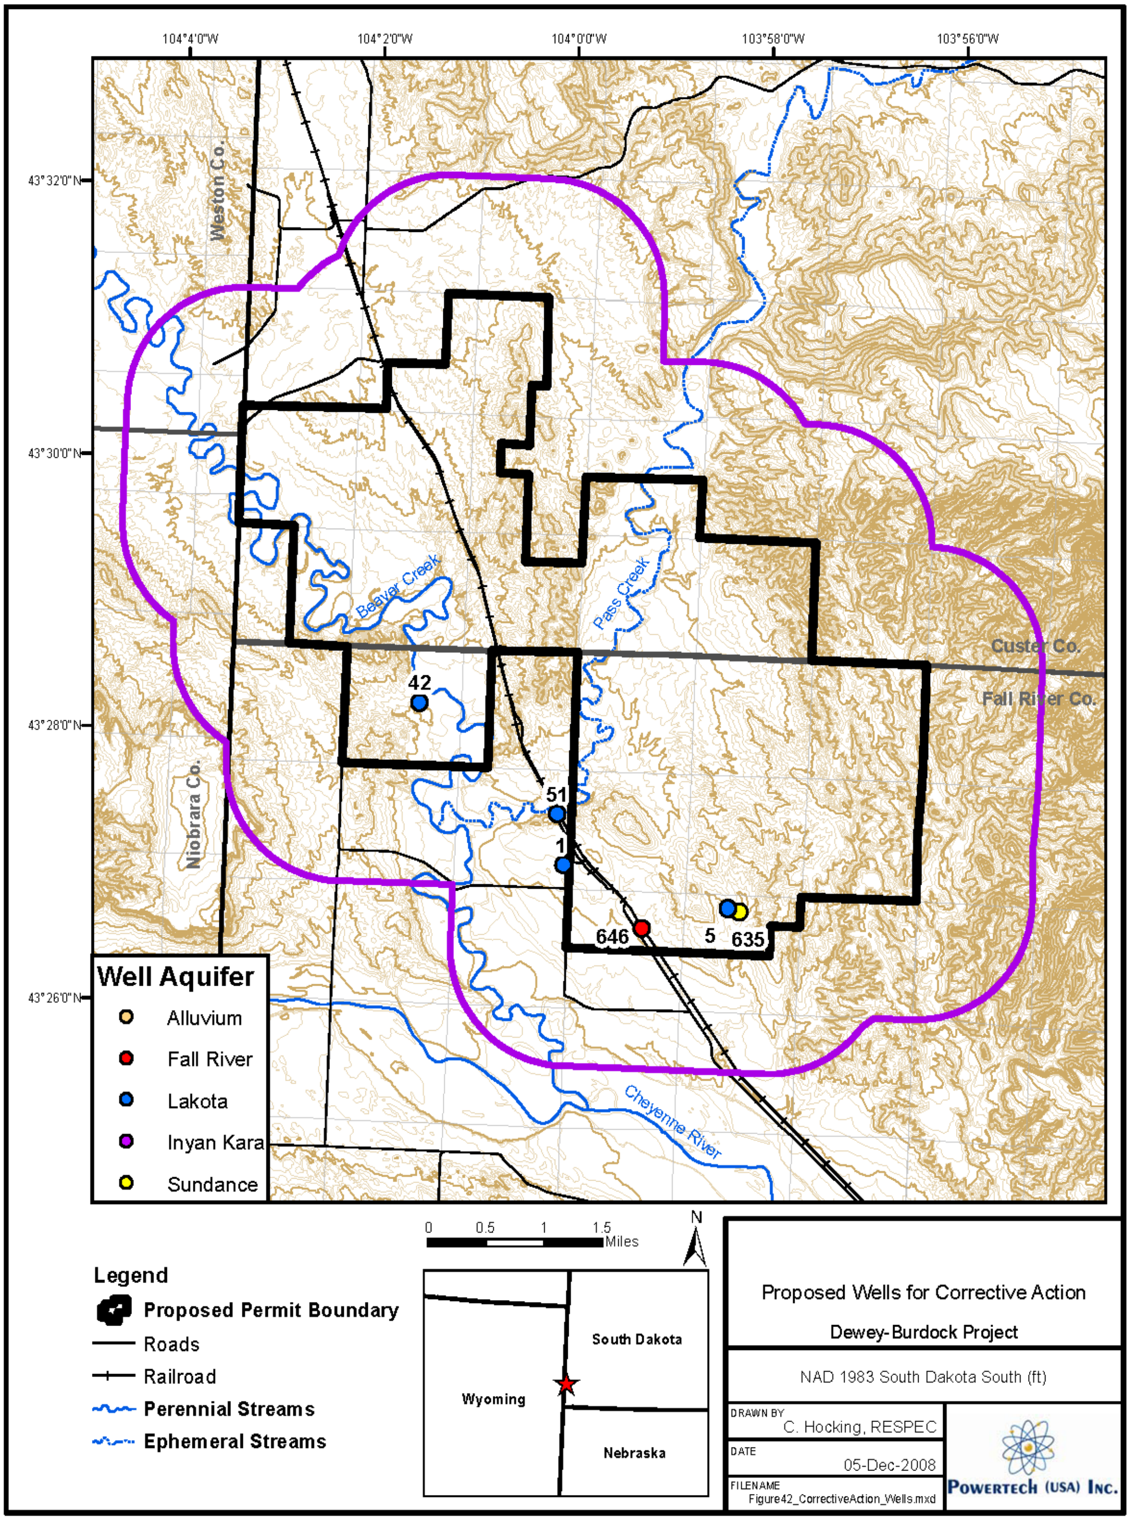

Figure 3.7-1 Proposed Wells for Corrective Action

3.8 Life of Mine Schedule/Sequence of Operations

Following the issuance of an NRC uranium recovery license and other relevant permits it is anticipated that construction of the Burdock Well Field 1, CPP and ancillary facilities including storage ponds and land application pivots will commence. The construction of the Dewey Well Field 1 and ancillary facilities will follow shortly thereafter. Startup of the Dewey and Burdock operations will commence upon completion of construction and will continue for approximately 7 to 20 years or more during which additional well fields will be completed along the roll fronts at both Dewey and Burdock sites. It is planned that groundwater restoration can be accomplished within NRC requirements for timeliness in decommissioning (10 CFR § 40.42); however, in the event restoration cannot be accomplished within this timeframe, Powertech (USA) will seek NRC approval for an alternate schedule. The projected construction, operation, restoration and decommissioning schedule is provided in Figure 3.8-1.

Decommissioning of the well fields including well abandonment, the removal of piping, tanks, ancillary buildings and equipment, cleanup of surface soil to applicable standards and revegetation of disturbed areas will be implemented following the cessation of ISL operations at the Dewey and Burdock sites. It is likely that the CPP at the Burdock site will continue to operate for several years following the decommissioning of the Proposed Action well fields. The CPP may continue to process uranium from other ISL projects such as the nearby Powertech (USA) satellite ISL projects of Aladdin and Dewey Terrace planned in Wyoming, as well as possible tolling arrangements with other operators.

POWERTECH (USA) INC.

Figure 3.8-1 Projected Construction, Operation, Restoration and Decommissioning Schedule

3.9 Infrastructure Plans

Approach to Well Field Development

An ISL well field consists of a series of injection and production wells that are completed across the target mineralization zone. Prior to design of the wells, the ore bodies will be delineated with exploration holes drilled on 100-feet centers. As discussed earlier, these holes will be geologically and geophysically logged Using this information, each new injection and production well will be assigned lateral coordinates, a ground surface elevation, depth to base of casing, i.e., top of completion interval, and length of completion interval, before it is drilled.

For all injection and production wells, the base of casing will be established at or below the confining unit overlying the mineralized zone. The screened interval will be completed only across the targeted ore zone.

A typical (100 x 100 ft grid) well field layout is illustrated on Exhibit 3.9-1 This typical layout is based on the lateral distribution and grade of one of the uranium deposits within the PAA.

The well field patterns may differ from well field to well field, but a typical pattern will consist of five wells, with one well in the center and four wells surrounding it oriented in four corners of a square between 50 and 150 feet. Typically, a production well is located in the center of the pattern, and the four corner wells are injection wells. Such a pattern will be modified as needed to fit the characteristics of each orebody.

The pattern dimensions will vary depending on the geometry of the orebody. All wells will be completed so they can be used as either injection or production wells, so that well field flow patterns can be changed as needed to improve uranium production and restore groundwater quality in the most efficient manner. Other well field designs that may be considered include alternating single lines of production and injection wells.

Production and injection wells will be connected to a common header house, as depicted in Exhibit 3.9-2. Well head connection details for injection and production wells are illustrated on Figures 3.9-1 and 3.9-2, respectively.

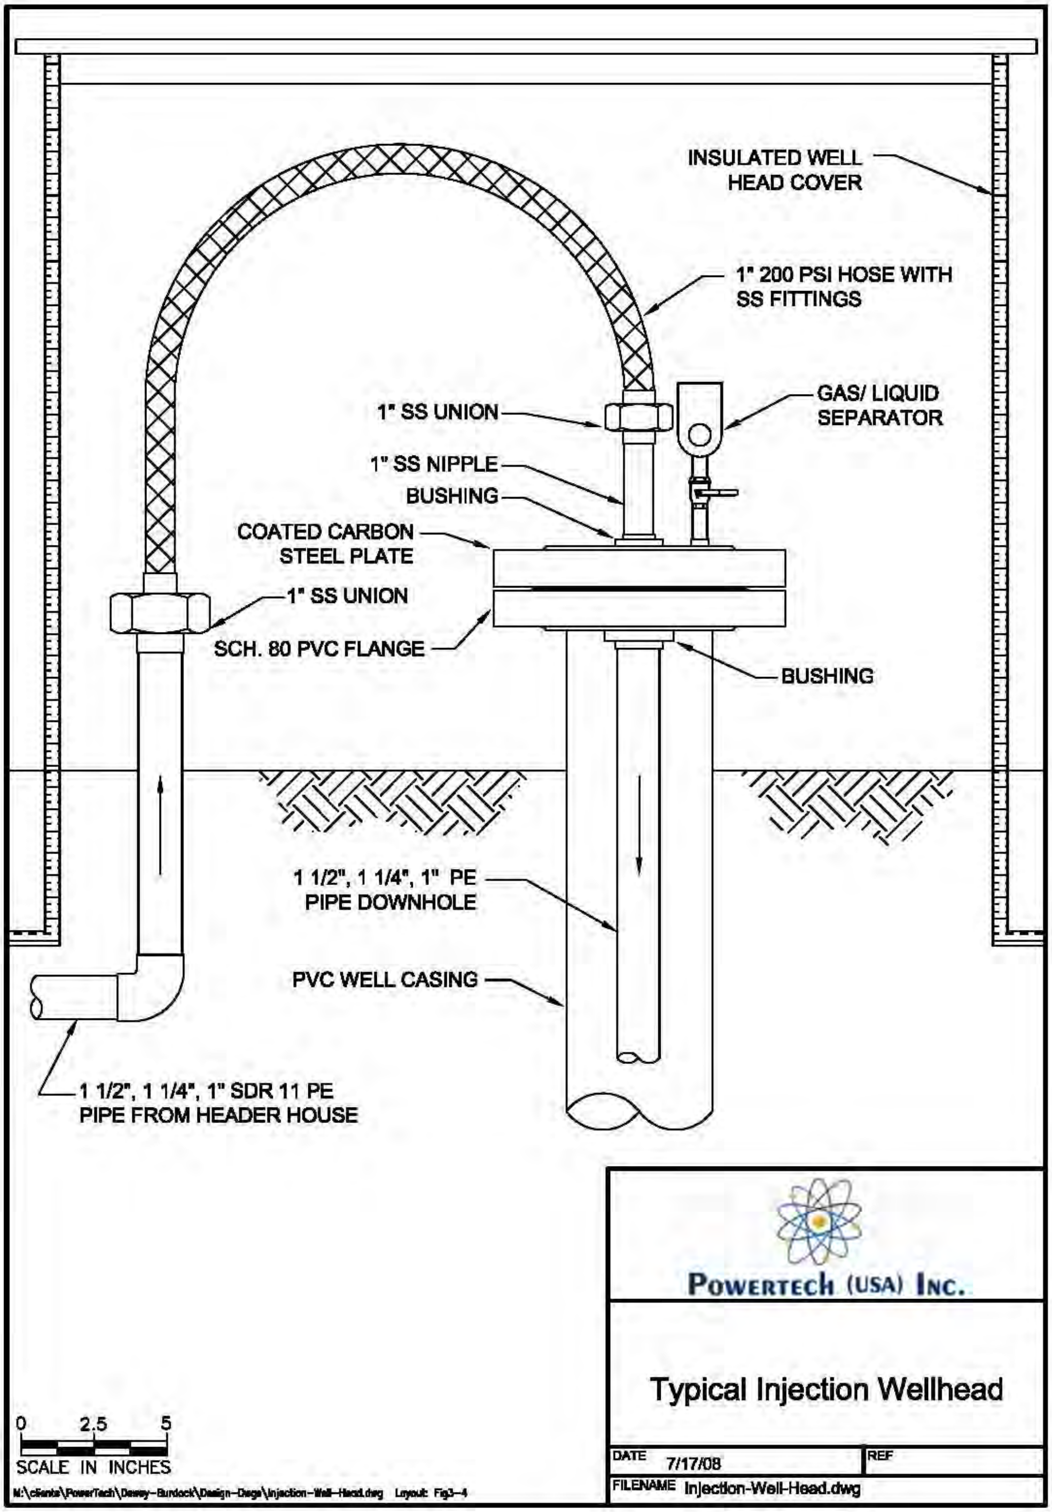

Figure 3.9-1 Typical Injection Wellhead Diagram

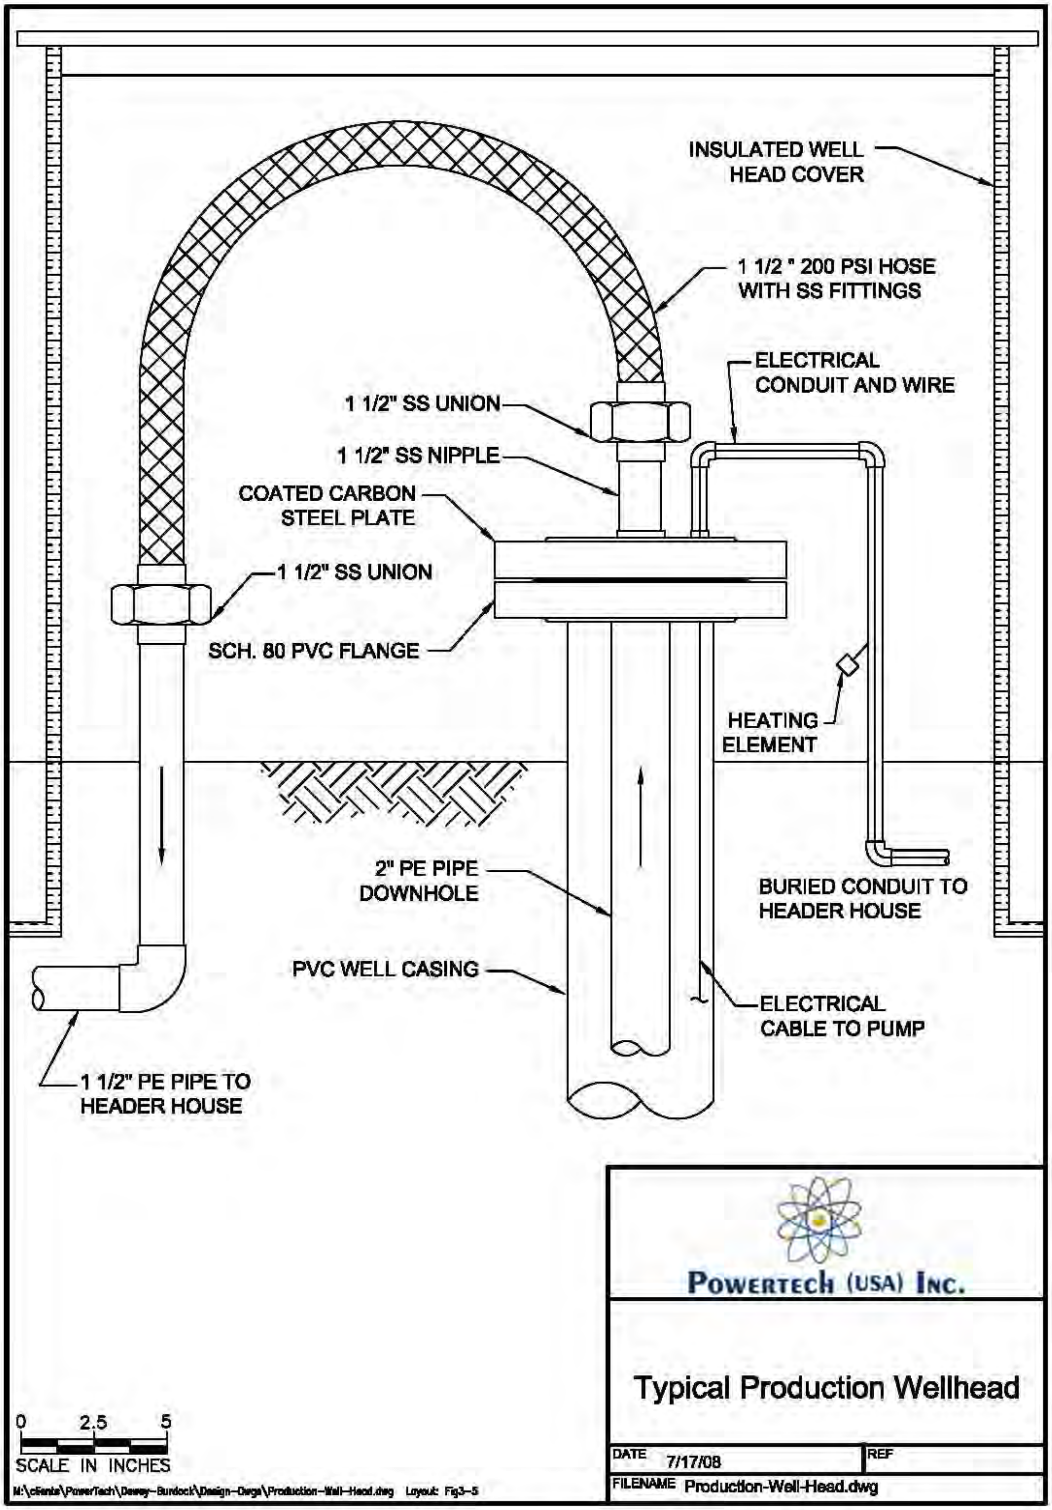

Figure 3.9-2 Typical Production Wellhead Diagram

Well Construction Methods

Typical well installation will begin with drilling a pilot bore hole through the ore zone to obtain a measurement of the uranium grade and the depth. The pilot bore hole will be described using geologic and geophysical logs. After logging, the pilot bore hole will be reamed to the appropriate diameter to the top of the ore zone. A continuous string of PVC casing will be placed into the reamed borehole. Casing centralizers will be installed as appropriate. With the casing in place a cement/bentonite grout will be pumped into the casing. The grout will circulate out the bottom of the casing and back up the casing annulus to the ground surface. The volume of grout necessary to cement the annulus will be calculated from the bore hole diameter of the casing with sufficient additional allowance to achieve grout returning to surface. Grout remaining inside the well casing may be displaced by water or heavy drill mud to minimize the column of the grout plug remaining inside the casing. Care will be taken to assure that at a grout plug remains inside the casing at completion. The casing and grout will then be allowed to set undisturbed for a minimum of 24 hours. When the grout has set, if the annular seal observed from the ground surface has settled below the ground surface, additional grout will be placed into the annular space to bring the grout seal to the ground surface.

After the 24-hour (minimum) setup period, a drill rig will be mobilized to finish well construction by drilling through the grout plug and through the mineralized zone to the specified total well depth. As illustrated in Figure 3.9-3, the open borehole will then be under reamed to a larger diameter.

A well screen assembly will then be lowered through the casing into the open hole. The top of the well screen assembly will be positioned inside the well casing and centralized and sealed inside the casing using “K” packers. With the drill pipe attached to the well screen, a one-inch diameter tremie pipe will be inserted through drill pipe and screen, and through the sand trap check valves at the bottom of well screen assembly. Filter sand, comprised of well rounded silica sand sized to optimize hydraulic communication between the target zone and well screen, will then be placed between the well screen and the formation. The volume of sand introduced will be calculated such that it fills the annular space. The sand will not extend upward beyond the K packers due to packer design. A well completion report will then be prepared for each well. The reports will be kept available on-site for review.

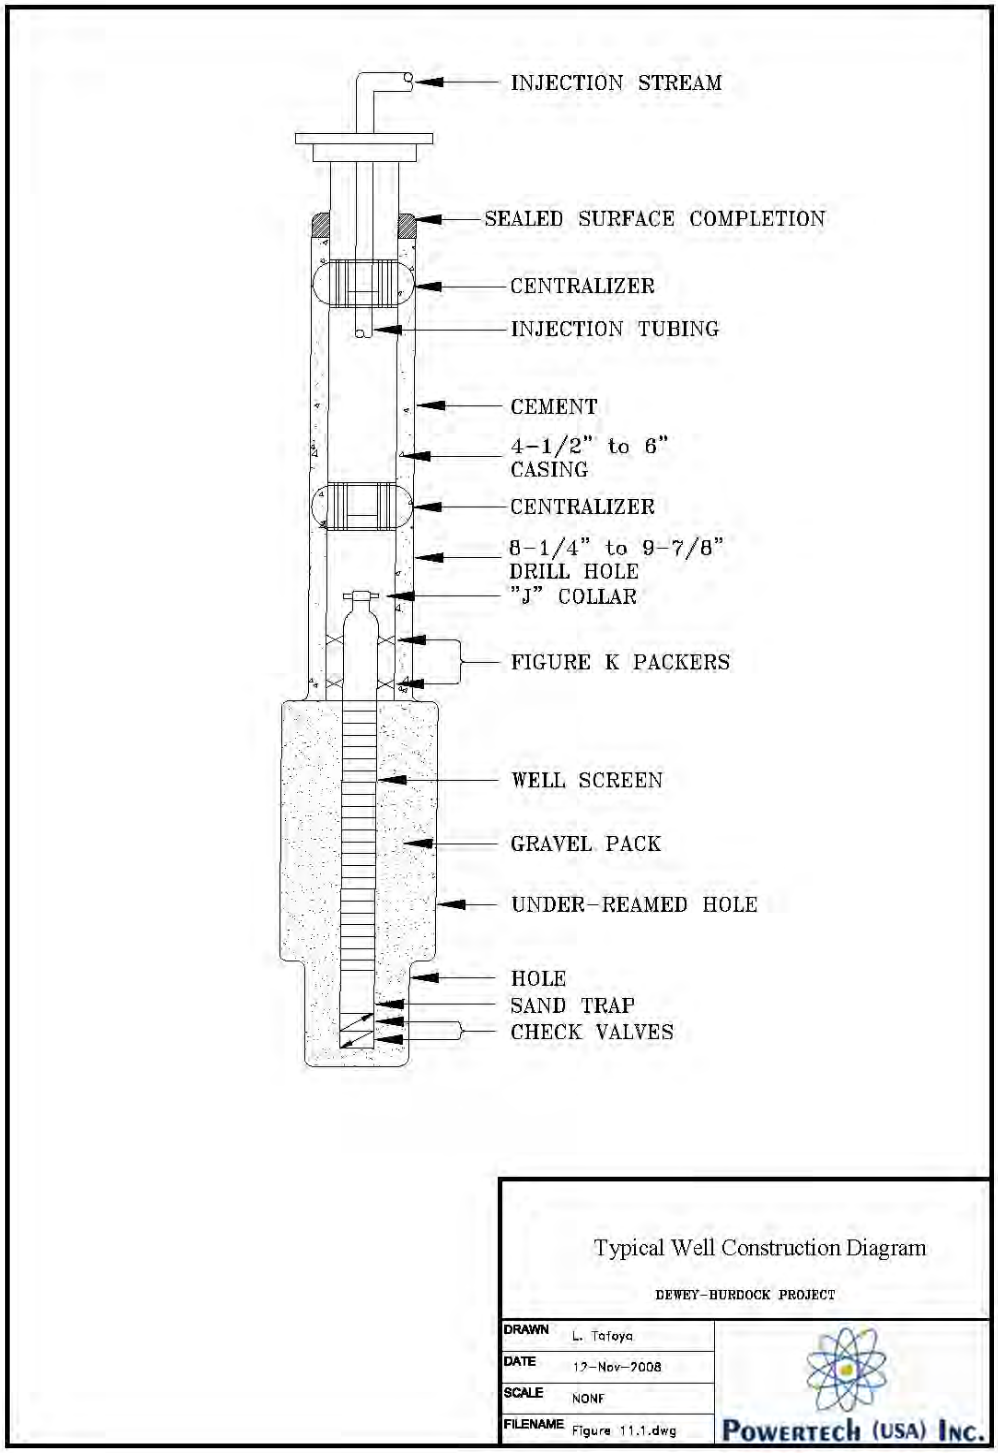

Figure 3.9-3 Typical Well Construction Diagram

The primary goals of well development are to allow formation water to enter the well screen and flush out drilling mud, or cement filtrate water and to develop the well bore to remove the finer clays and silts to reduce the pressure drop between the formation and the well screen. This process is necessary to allow representative samples of groundwater to be collected, if applicable, and to ensure efficient injection and production operations. Wells will be developed immediately after construction using air lifting, swabbing, pumping or other accepted development techniques which will remove water and drilling fluids from the casing and borehole walls along the screened interval. Prior to obtaining baseline samples from monitor or restoration wells, additional well development will be conducted to ensure that representative formation water is sampled. The water will be pumped sufficiently to show stabilization of pH and conductivity values prior to sampling and used to indicate that development activities have been effective.

Well Integrity Testing

Field-testing of all injection, recovery, and monitor wells will be performed to demonstrate the mechanical integrity of the well casing. The mechanical integrity test (MIT) will be performed using pressure-packer tests. The bottom of the casing will be sealed with a plug, downhole packer, or other suitable device. The casing will be filled with water and the top of the casing will be sealed with a threaded cap or mechanical seal. The well casing will then be pressurized with water or air and monitored with a calibrated pressure gauge. Internal casing pressure will be increased to 125 percent of the maximum operating pressure of the well field, 125 percent of the maximum operating pressure rating of the well casing (which is always less that the maximum pressure rating of the pipe), or 90 percent of the formation fracture pressure (which equates to approximately 1 psi per foot of overburden above the bottom of casing), whichever is less. Powertech proposed the method, upon stabilization of pressure, to take readings and record readings at two-minute intervals for ten minutes. A well passes the test if it holds 90 percent of the original pressure for ten minutes. DENR currently requires readings every five minutes for a period of fifteen-minutes after stabilization of pressure. EPA has a different guideline yet. Powertech (USA) is in close communication with the agencies and will comply with the appropriate duration for MIT for Class III wells.

If there are obvious leaks, or the pressure drops by more than 10 percent during the 10 minute period, the seals and fittings on the packer system will be checked and/or reset and another test will be conducted. If the pressure drops less than 10 percent the well casing will have demonstrated acceptable mechanical integrity.

If a well casing does not meet the MIT criteria, the well will be removed from service. The casing may be repaired and the well re-tested, or the well may be plugged and abandoned. Plugging of wells will be in accordance with the EPA regulations located in Title 40 Part 146.10 which comply with the South Dakota Administrative Rules contained in Chapter 74:55:01:59. DENR will be notified of any well that fails the MIT. If a repaired well passes the MIT, it will be employed in its intended service following approval from EPA and/or DENR that the well has demonstrated mechanical integrity. If an acceptable test cannot be demonstrated following repairs, the well will be plugged and abandoned.

In addition to the integrity testing of new wells, a MIT will be conducted on any well following any repair where a downhole drill bit or under-reaming tool is used. Any injection well with evidence of suspected subsurface damage will require a new MIT prior to the well being returned to service. Mechanical integrity tests will also be repeated once every five years for all active wells.

The MIT of a well will be documented to include the well designation, date of test, test duration, beginning and ending pressures, and the signature of the individual responsible for conducting the test. Results of the MITs will be maintained on-site and will be available for inspection by EPA and DENR. Results of MIT shall be reported within quarterly reports in accordance with the EPA UIC regulations in Title 40 Part 146.33 which also meet the DENR requirements in § 74:55:01:49.

3.9.1 Monitoring Well Layout and Design

An extensive groundwater sampling program specific to each well field will be conducted prior to, during, and following ISL operations to identify any potential impacts to water resources of the area. The groundwater monitoring program for individual well fields is designed to (1) establish baseline water quality prior to production, (2) detect excursions of lixiviant either horizontally or vertically outside the of the target mineralization zone, (3) demonstrate compliance with groundwater quality standards, and (4) determine when the mined mineralized zone has been adequately restored following ISL operations. Objectives 1 (partially) and 4 will accomplished using injection and recovery wells. Objectives 1 (partially), 2, and 3 will be accomplished using perimeter and internal non-production zone monitoring wells.

The production wells are laid out in a regular grid to efficiently contact the mineralized deposit (Figure 3.9-4). Generally, the wells are laid out in regular geometric shapes, usually squares, rectangles, triangles, or hexagons. The important features are that the patterns cover the economically mineable portions of the orebody, the production (pumping) well is in the center of each geometric shape, the injection wells are equally spaced from each other and from the production wells in each pattern (geometric shape). This is to ensure efficient contacting of the ore by uniform flow distribution and to facilitate control of the flow to prevent excursion of leachate to the monitor well ring. The injection wells are on the outside to ensure the ore is contacted with leachate and a bleed withdrawing of some 0.5 to 3 per cent of the leachate circulating to maintain a cone of depression ensuring outside groundwater in the ore zone flows in toward the production well field to prevent flow of leachate outwards (NMA, 2007).

The production zone monitor wells are completed in the ore zone around the perimeter of the production well fields spaced 400 feet outside the production well field and evenly spaced around the perimeter of the well field with a minimum spacing either 400 feet or the spacing that will ensure a 70 degree angle between adjacent production zone monitor wells and the nearest injection well (NUREG/CR-6733; NUREG-1910, 2008; NUREG-1569).

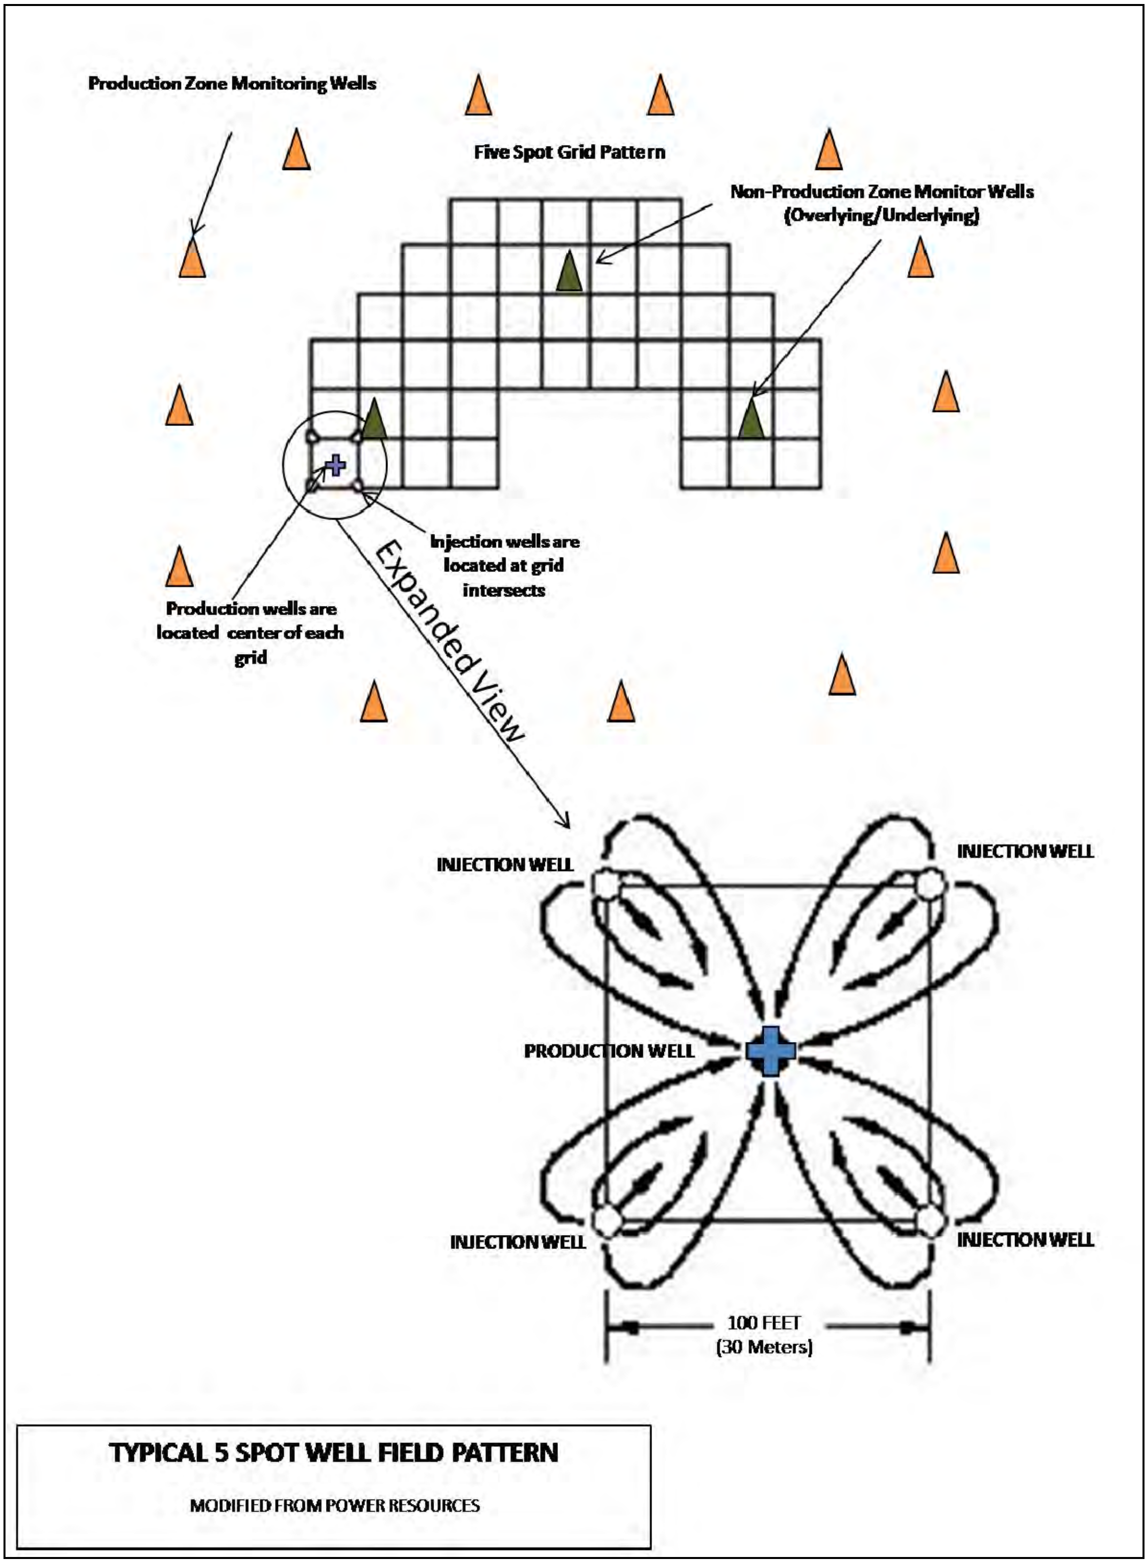

Figure 3.9-4 Typical 5 Spot Well Field Pattern

Non-Production Monitoring Wells
Depending on-site specific conditions, non-production monitoring wells may consist of two types of monitor wells termed "overlying" and "underlying". The screened intervals of overlying wells are located in the sand unit or aquifer immediately above the ore-bearing stratum. The overlying non-production monitoring wells are designed to provide monitoring of any upward movement of leach fluids that may occur from the production zone and to guard against potential leakage from production and injection well casing into any overlying aquifer. The overlying wells are used to obtain baseline water quality data and are used in the development of UCLs for the overlying zones that will be used to determine if vertical migration of leach fluids is occurring. Vertical monitoring is generally set up with a density of wells ranging from one every three or five acres and where confining layers are very thick and permeabilities are negligible, requirements for vertical excursion monitoring can be relaxed or eliminated for underlying aquifers (NUREG/CR-6733, 2001). The screened zone for the overlying wells is determined from electric logs by qualified geologists or hydrogeologists. The first layer of overlying non-production zone monitoring wells will be evenly distributed through the production area with a minimum of one well for every four acres of production area. Should additional aquifers exist above the first monitoring layer; additional overlying monitors will be located in these aquifers with a minimum of one well positioned for every eight acres of production area. The overlying wells will be placed within the geology just above the PAA's upper confining layer the Skull Creek Shale; it has a thickness of approximately 200 feet. Core samples were collected from the lower Skull Creek Shale; analyses of these core samples demonstrate that the Skull Creek Clays have extremely low vertical permeabilities, in the range of 6.8 x 10-9 cm/sec (0.007 millidarcies).

A single layer of underlying monitor wells may be completed in the first sand unit or aquifer underlying the ore-bearing stratum similarly based on the local lithology. The underlying monitor wells are used to obtain baseline water quality data and are used in the development of UCLs for the underlying aquifer that will be used to determine if vertical migration of leach fluids is occurring. The screened zone for the underlying monitor wells is determined from electric logs by qualified geologists or hydrogeologists. Underlying non-production monitoring wells will be evenly distributed through the production area with a minimum of one well for every four acres of production area. Underlying wells will not be installed below the Lakota formation, primarily due to the presence of the approximately 100' thick and relatively impermeable Morrison formation immediately below the Lakota formation.

Non-production zone monitoring wells will be designed and installed for detection of potential excursions of lixiviant, if such an excursion were to occur. Design of the monitor ring and overlying and underlying monitor wells will be performed for each well field according to site specific lithology and processes of the production zone(s) of each well field. Powertech (USA) will present each monitoring well program to EPA and the South Dakota Department of Environmental Natural Resources (DENR) before installation of proposed well placement to ensure administrative approval is obtained. After completion of the required hydrologic test, it may be necessary to revise the location and/or number of wells proposed. South Dakota UIC Class III rules were promulgated in April 2008. ARSD 74:55:01:42 addresses non-production zone monitoring. The rule provides for alternative non-production zone monitoring well location and spacing to be considered if the operator demonstrates that the proposed location or spacing will adequately provide monitoring coverage. Based on industry experience in locating and spacing overlying monitor wells and the low probability of any upward fluid migration going undetected, along with considerations of local lithology, Powertech believes the proposed locations and spacing are sufficient for the monitoring of any potential upward migration of production fluids. The monitoring program will be designed in an effort to satisfy Title 40: Protection of Environment PART 146—Underground Injection Control Program: Criteria and Standards and Chapter 74:55:01 Underground Injection Control -- Class III Wells for the state of South Dakota.

Each well field will be handled on a case-by-case basis in consultation with the EPA and SD DENR. Powertech's Safety and Environmental Review Panel (SERP) to be established under NRC requirements will review hydrologic test results and documentation to demonstrate that the monitoring wells are not hydrologically connected to the injection or production wells. Well field packages will be evaluated based on current knowledge of site lithology and processes of the production area, and industry proven practices, the number and spacing of overlying and underlying monitoring wells to ensure number and spacing meets criteria to protect human health and the environment. Wells completed in overlying and underlying aquifers will be subject to sampling, remedial action, and reporting requirements pertinent to EPA and SD DENR rules.

Groundwater samples will be collected monthly for the first year of operation and quarterly thereafter at the groundwater monitoring well locations as shown in Figure 3.9-5. Quarterly samples will be collected from drinking water and livestock wells, included in the groundwater sampling sites as shown in Figure 3.9-5.

An extensive groundwater sampling program specific to each well field will be conducted prior to, during, and following ISL operations to identify any potential impacts to water resources of the area. The groundwater monitoring program for individual well fields is designed to: (1) establish baseline water quality prior to production, (2) detect excursions of lixiviant either horizontally or vertically outside the of the target mineralization zone, (3) demonstrate compliance with groundwater quality standards, and (4) determine when the mined mineralized zone has been adequately restored following ISL operations. Objectives 1 (partially) and 4 will accomplished using injection and recovery wells. Objectives 1 (partially), 2, and 3 will be accomplished using perimeter and internal non-production zone monitoring wells.

The fact that the upper confining layer is approximately 200-feet-thick and the lower confining layer is approximately 100-feet-thick significantly reduces the concerns of a potential vertical breach for lixiviant migration.

Approximate placement for both well types are illustrated on Figure 3.9-6 and discussed below.

Powertech (USA) Inc.

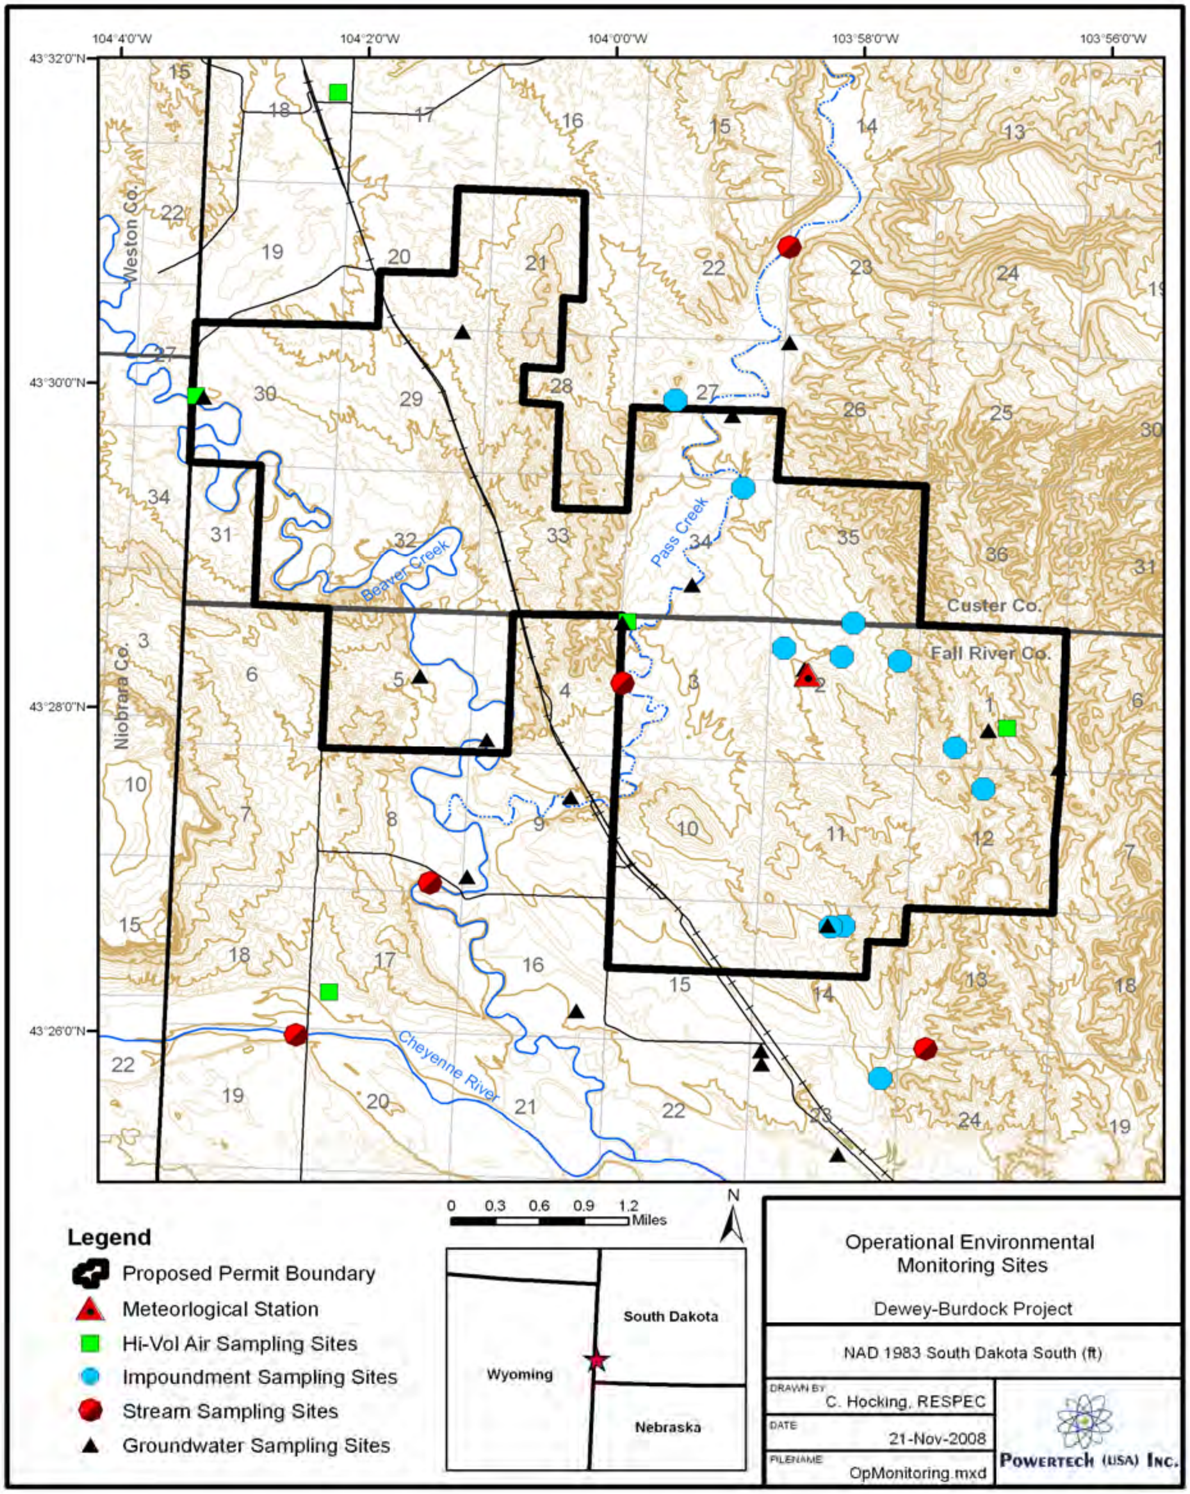

Figure 3.9-5 Operational Environmental Monitoring Sites

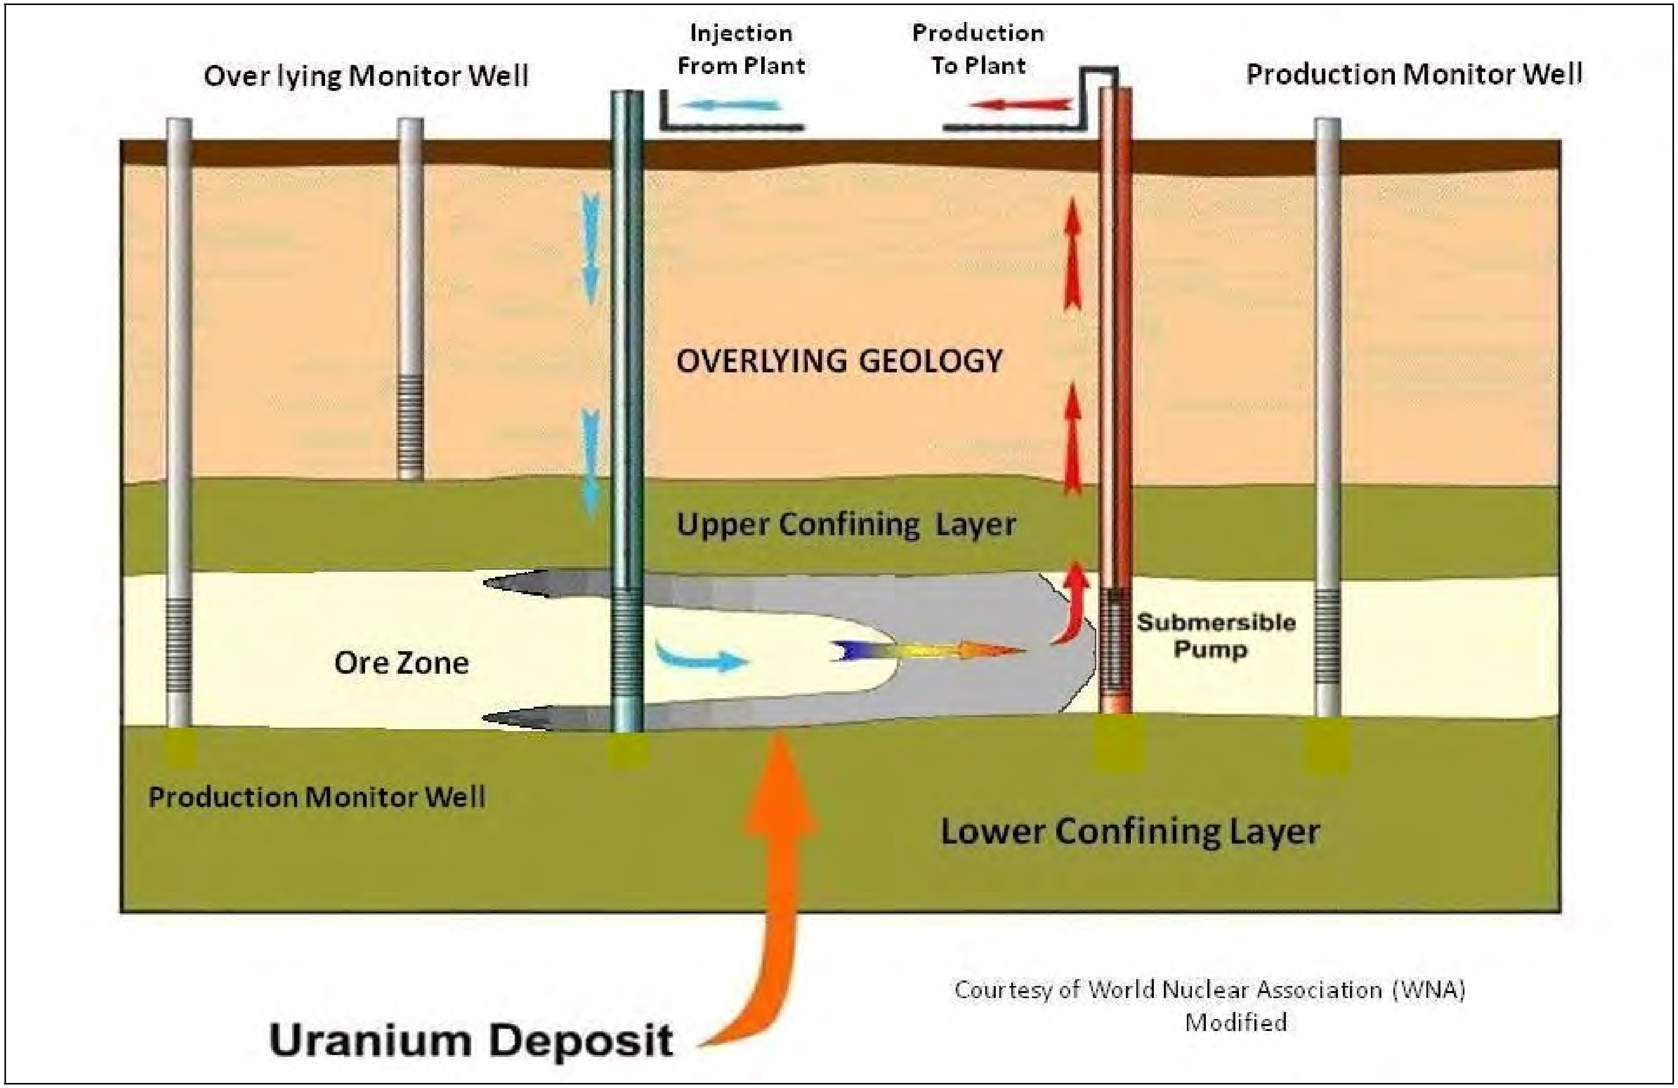

Figure 3.9-6 Cross Section of Typical Well Placement

Production Monitoring Wells

Production zone monitoring wells are installed around the periphery of each production area to monitor for any fluids that might escape the hydraulic controls (Hunkin, G. G., 1977 and Dickinson, K. A., and J. S. Duval, 1977), with a screened interval open to the sand unit containing the production zone. This monitoring “ring” design serves two purposes: (1) to monitor any horizontal migration of fluid within the sand unit or aquifer where production is occurring and, (2) to determine baseline water quality data and characterize the area outside the production pattern area. Upper Control Limits (UCLs) are determined from indicator constituents that are selected due to their nature of mobility to provide early warning with regards to a potential excursion; these constituents are determined from the well field specific groundwater quality baseline data. By establishing UCLs, the operator is allowed the capability of early detection of an excursion at a monitor well and then has the time to apply corrective action before water quality outside the aquifer exemption boundary is adversely affected (NUREG/CR-6733, 2001). Production zone monitor wells will be located no more than 400 feet from the production area, and will be spaced no more than 400 feet between production zone monitoring wells (NUREG/CR-6733; NUREG-1910, 2008; NUREG-1569). If the monitor wells are closer than 400 feet to the well field, the monitor wells will be located via a strategic distance to maintain a minimum angle between Monitor wells and the nearest injection well of 70 degrees. This will ensure that no leach fluids will pass between the adjacent monitor wells undetected as the leach fluids would flow radially outward from the initiation point of an excursion. Production zone monitoring wells are installed before the start of production activities in order that required baseline sampling and hydrologic tests can be conducted. Well design, construction, and development will be identical to those of injection and recovery wells, except well screens will be completed across the entire mineralized sandstone (Figure 3.9-7).

An extensive groundwater sampling program specific to each well field will be conducted prior to, during, and following ISL operations to identify any potential impacts to water resources of the area. The groundwater monitoring program for individual well fields is designed to: (1) establish baseline water quality prior to production, (2) detect excursions of lixiviant either horizontally or vertically outside the target mineralization zone, (3) demonstrate compliance with groundwater quality standards, and (4) determine when the mined mineralized zone has been adequately restored following ISL operations. Objectives 1 (partially) and 4 will be accomplished using injection and recovery wells. Objectives 1 (partially), 2, and 3 will be accomplished using perimeter and internal non-production zone monitoring wells. Monitoring safeguards utilized during operational phase include monitoring the rates, volumes and wellhead pressures of production and injection wells. Monitor well sampling will also be conducted during restoration, including stabilization monitoring at the end of the restoration activities to determine the achievement of acceptable water quality.

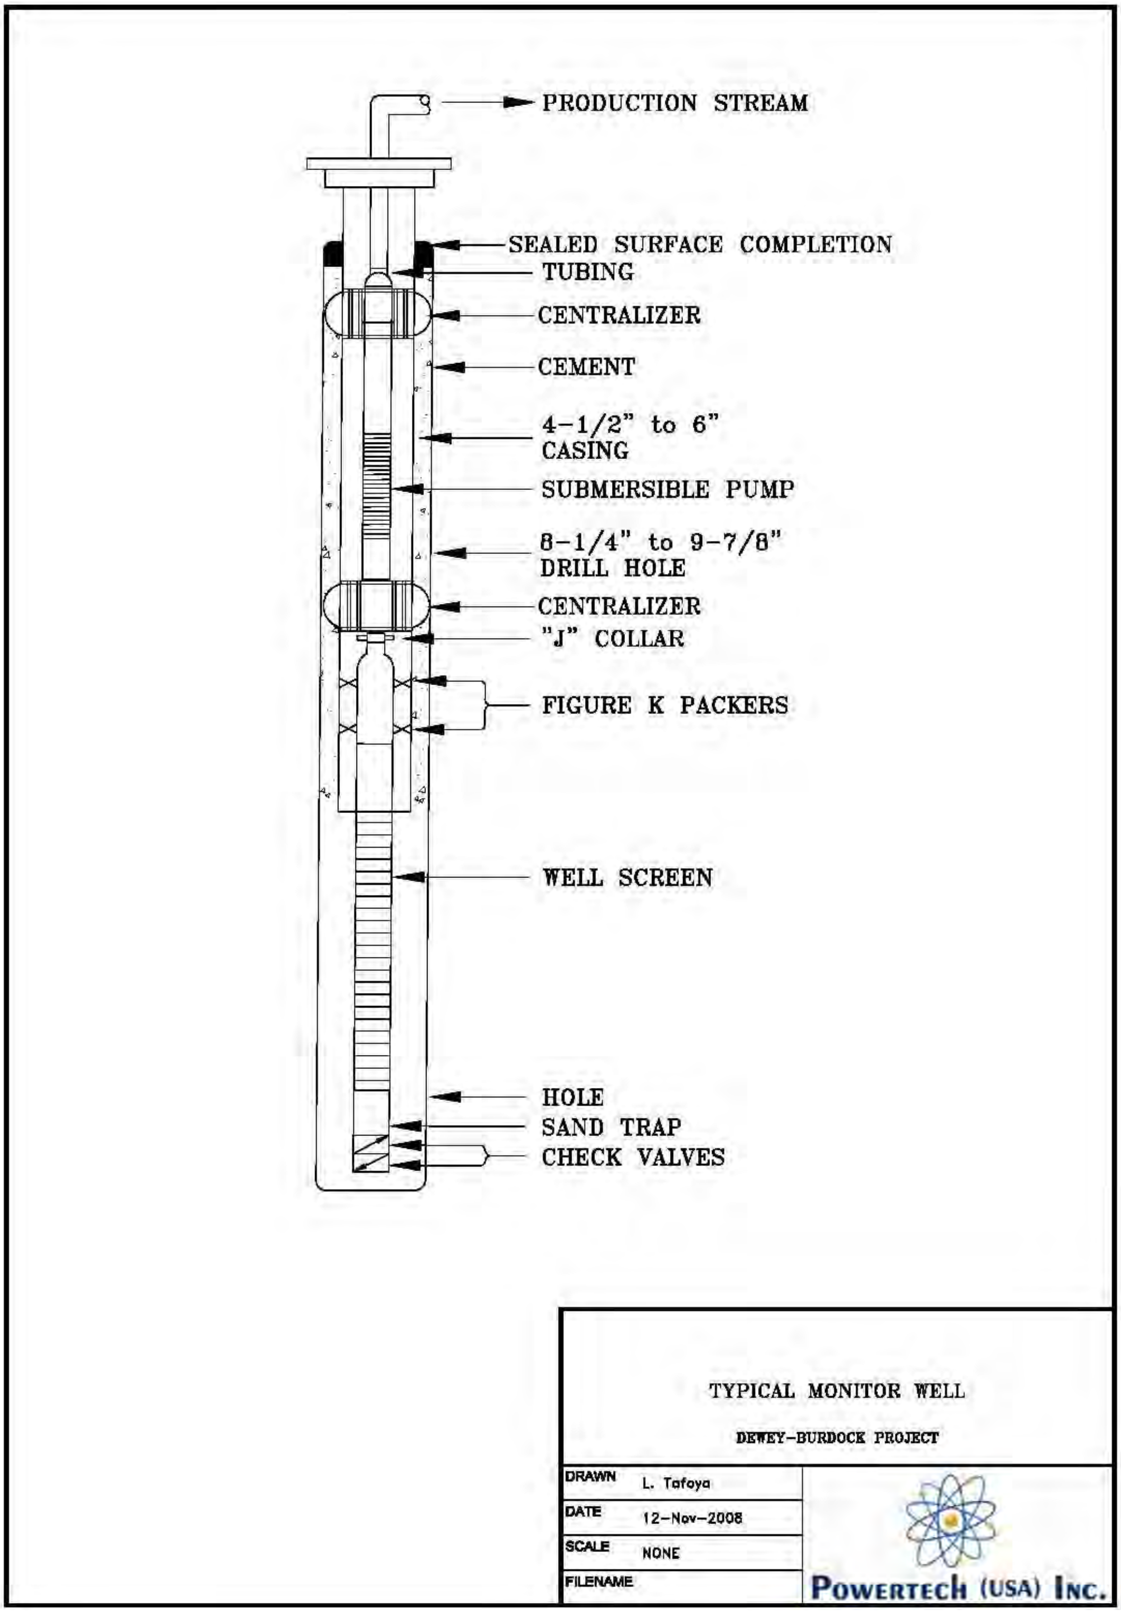

Figure 3.9-7 Typical Monitor Well Construction Diagram

Section 4.0 - Reclamation, Restoration and Facility Decommissioning Plan

Groundwater restoration, reclamation of disturbed land and decommissioning of the well fields, plant and associated facilities will be conducted in a manner that will protect human health, safety and the environment. The methods for achieving this objective are discussed in the following sections.

The reclamation and decommissioning plan presented within this document was prepared in accordance with 43 CFR § 3809, ARSD 74:29:08, SDCL 45-6B-81 and NRC 10 CFR Part 20 Subpart E. The plan has been designed to implement concurrent reclamation, upon affected lands which will not be disturbed again and where it will not adversely affect other mining operation activities, during all phases of mining in order to reclaim disturbed areas at the earliest feasible time, by taking reasonable measures to prevent and/or control on-site and off-site damage of the affected lands (§ 3809.420(3)(i)).

4.1 Surface Reclamation and Decommissioning

The estimated annual surface disturbance for the life of the PA is a maximum of 108 acres. The following are proposed actions to be taken to reclaim surface disturbance.

The Best Management Practices (BMPs) are intended as general guidance to assist individuals responsible for management of activities aimed at reducing, preventing and/or controlling on and off-site damage of the affected lands 74:29:07:02. The BMPs have been selected on the basis of site-specific and industry specific conditions that reflect natural background conditions and will be implemented and applied as a system rather than a single practice. The system employed by Powertech (USA), has been selected and designed to effectively maintain each area in such a manner as to require minimal reclamation rehabilitation effort due to the use of BMPs that implement the front-end of reclamation practices. The BMPs utilized, ensure steps are taken throughout the life of the project that are protective of human health and safety and the environment. The goal of surface reclamation is to release the property for wildlife habitat. This will be accomplished by stabilization with self-sustaining vegetative cover. Due to the over grazed nature of large portions of the properties; the reclamation system is expected to substantially improve the properties upon Powertech's departure. The treatments for revegetation will utilize indigenous species selected for their value as cover and food for both domestic and native fauna. Vegetation will be selected with soil stability and water conservation as considerations. The use of other more specific BMPs as developed by government agencies such as the Soil Conservation Service (SCS), Bureau of Land Management (BLM), EPA and the Army Corp of Engineers may be proposed. However, the BMPs proposed here are expected to be compatible with requirements of governing agencies. The BMPs will be planned and implemented with full consideration for existing resources and site specific conditions. The planning process implemented will consider economics and compatibility with existing operations. The BMPs proposed here will be used to remediate and/or prevent damage that may occur due to construction and resource extraction practices.

A final decommissioning and reclamation plan will be submitted to the NRC and DENR for review and approval at least 12 months prior to the planned decommissioning of a well field or PAA. The reclamation strategy will be developed in accordance with the state requirements for wildlife habitat in 74:29:07:22. Any changes that occur in the approved reference area which may affect the usefulness of reclamation success will be reported to DENR in writing.

4.1.1 BMPs Proposed for Surface Disturbance during Construction and Operation

As stated above, the average maximum estimated land disturbed per year for the life of the operation is 108 acres. The following proposed procedures will be used to minimize the impacts of surface disturbance during construction and operation:

- Disturbance will be limited to only what is necessary for operations.
- Development of Quality Assurance Quality Control (QA/QC) plan to monitor the effectiveness of mitigation methods.
- Restrict normal vehicular traffic to designated roads and keep required traffic in other areas of the well field to a minimum. Road construction and/or upgrades to reads and railroad spurs that provide exclusive service to the Powertech (USA) mining operations will be conducted in compliance with ARSD 74:29:07:12.
- Use Class V deep disposal wells for disposal of liquid wastes to mitigate potential land use impacts. Land application may be utilized separate or in conjunction with a Class V and is dependent upon federal authorization of a Class V permit.
- Disposal of refuse will be disposed of in an approved landfill and/or disposed of on-site if disposal complies with the SD solid waste regulation in article 74:27. Any acid forming or toxin-producing material will handled and disposed of in a manner that controls unsightliness and protective of existing hydrologic systems Hazardous wastes will be handled in accordance with state and federal hazardous waste regulations.
- Conduct site ISL reclamation in interim steps to minimize potential land use environmental impacts. As noted above, sequential well field development results in minimizing land area impacted at any one time.
- Stockpile topsoil from the well sites, evaporation ponds, and facilities. Shape, seed the piles with a cover crop or mulch the stockpiles to control erosion.
- Spoil material on affected lands will be handled in accordance with ARSD 74:29:07:14.
- Grading and backfilling may be necessary to reconstruct topographic features to achieve the functionality and visual compatible contours of pre-mining status. Grading and backfilling performed upon the affected lands will be conducted in accordance with 74:29:07:04.
- Evaporation or water treatment ponds, if used, will be reclaimed and re-vegetated and the land returned to its previous uses, or as otherwise agreed with the regulatory entities and landowners.
- After groundwater restoration is completed, properly decommission each well field and remove or decontaminate in place all well field lines and pipelines. Upon decommissioning, all wells will be sealed and capped. As areas are restored, they will be backfilled, contoured, and smoothed to blend with the natural terrain in accordance with the surface reclamation plan.
- All process facilities will be decontaminated and removed unless they are to be used for other future activities; the Permit Area will regain its pre-operational features.

Upon completion of final site D&D, including surface reclamation, landowners will be contacted and given the option to retain the roads for their private use or have the roads reclaimed by Powertech (USA). If the roads are deemed beneficial to others (i.e., hunters, ranchers and residents) and the landowner agrees, the roads will not be reclaimed. Only roads related to the Proposed Action will be reclaimed.

4.1.2 Topsoil Management

Definition: The salvaging, stockpiling and reapplication of topsoil or other selected materials to be used as growth medium in the reclamation of surface disturbances.

Purpose: To re establish stability and productivity of acreage subject to surface disturbance through proper soils management in accordance with SDAR 74:29:07:07.

Applicability: Although there is very little earthwork associated with ISR activities as compared to open pit mines, proper topsoil management is a priority to ensure successful surface reclamation where surface disturbance does occur.

Topsoil will be salvaged in advance of construction from building sites, permanent storage areas, primary and secondary access roads, chemical storage areas, header house locations, mud pit locations, and pipeline trench construction areas, in accordance with SD DENR requirements as specified in the large scale mine permit application. Earth moving equipment such as rubber-tired scrapers and front-end loaders will be used. Backhoes and excavators may also be used where pipeline trenches and mud pits are dug.

In areas that will be disturbed for prolonged periods during the life of the project (i.e., more than one construction season), topsoil will be salvaged and stored in designated topsoil stockpiles designed in accordance with SD DENR requirements as specified in the large scale mine permit application to minimize erosion. In the case of pipeline trenches, topsoil will be returned following pipeline installation and in the case of mud pits, topsoil will also be returned once use of the mud pit is complete.

The topsoil salvage depth is estimated from the baseline soil survey to range between 0 and 5 feet across the project area and average less than 2 feet. Final salvage depths and cutoff criteria will be determined based on construction level designs and additional soil testing in accordance with SD DENR requirements specified in the large scale mine permit application.

Topsoil salvaged from the primary access roadbed will be placed near the access road, including potentially on BLM-administered lands. Final stockpile locations and volumes will be determined based on construction-level road designs.

All topsoil and spoil stockpiles within the project area will conform to SD DENR requirements, which are described in the large scale mine permit application, to avoid erosion and preserve soil viability.

The topsoil thickness at the time of reclamation will be determined by dividing the area requiring topsoil replacement by the volume of topsoil salvaged from that area.

Planning Criteria: The following items will be considered while managing topsoil.

- The amount of surface disturbance (area), which may require topsoil or growth medium and the required depth of application
- The amount and quality of topsoil and/or growth medium selected
- Methods utilized for topsoil salvage
- Storage location, duration and protection of stockpile to prevent erosion
- Feasibility of direct replacement of the salvaged soils
- Availability and cost of additional growth media as a supplement to topsoil replacement, if necessary

Methods and Materials:

- Conduct a site specific soil survey of the project area as a part of baseline investigations. The soil survey will identify the soils suitable for salvaging, their depth and amount prior to disturbance.

- All suitable topsoil and suitable material to be utilized in reclamation of the surface disturbance should be salvaged wherever feasible and stockpiled for reapplication.
- Topsoil stockpiles will be marked with legible signs containing letters not less than six inches high in sufficient locations to clearly identify stockpiles. Such signs will be in place from the time stockpiling begins.
- If conditions permit, or if project schedules can accommodate, topsoil or growth medium should be applied directly to re contoured disturbance areas.
- Stockpiled soils should be properly stored and re vegetated to protect from erosion and the loss of vital organisms within the soil.
- Soil replacement depths are determined by several factors including: pre-disturbance soil depths, vegetation types and the physical and chemical properties of the material being covered.

Maintenance:
Regarding periodic maintenance, based upon the anticipated length of time the soils will be stockpiled, the piles will be covered with plastic or another substrate to protect from wind, rain and erosion. If storage will be for a long period of time, the stockpiles will be seeded with either annual or perennial grasses. This will stabilize the stockpiles surface. Other mechanisms may be proposed and may include covering stockpiles with plastic or canvas tarps or rock mulches.

Effectiveness:
Proper topsoil management will result in successful revegetation of surface disturbances, reduce soil erosion, and initiate the restoration of the surface disturbance areas stability and productivity.

4.1.3 Erosion Control

In the past, ISL facilities adopt best construction practices to prevent or dramatically decrease erosion (NUREG-1910). Many facilities have been operated to minimize erosion and surface disturbance and then assiduously restored affected soils effectively leaving little impact on soils (NMA, 2007). Surface runoff diversions and erosion control will be performed in accordance with ARSD 74:29:07:09. Diversions of intermittent and perennial streams are unlikely to occur, however, if such a necessity arises, diversion(s) will be conducted in compliance with ARSD 74:29:07:10.

Definition:
Erosion and sediment control structures encompass a host of specific structures that are designed to control a variety of potential surface drainage, erosion effects.

Purpose:
To protect the watershed(s) and the natural resources via a host of BMPs:

- Prevention of the formation of , or the promotion of gullies and rills
- Reduce flow velocity and/or provide structures capable of withstanding intermittent high velocity flows
- Stabilization of the grade and control of head cutting in natural or artificial channels
- Directing water from one elevation to another
- Diverting water away from unstable areas (slopes)
- Filtering and retaining sediment
- Applicability: These practices will be considered where site specific condition may result in:
  - Flow velocity is such that structures are required
  - Excessive grade conditions occur
  - Water needs to be moved from higher to lower elevations

– Sheet erosion results
– Establishment of vegetation cover
– Diversion of water from one area to another more stable area
– To prevent sedimentation or erosion in problem areas

Methods and Materials:

- Use erosion and run-off control features such as proper placement of pipe, grading to direct run-off away from water bodies, and use of riprap (broken rock and/or concrete) at these intersections to make bridges or culverts more effective, if necessary.
- Use sediment trapping devices such as hay or straw bales, fabric fences, and devices to control water flow and discharges to trap sediments moved by run-off
- Maintain natural contours as much as possible, stabilizing slopes and avoiding unnecessary off-road travel with vehicles
- Utilization of water bars or water breaks

Maintenance:
Regular inspection, maintenance and repairs will be performed according to the specific needs of the project site. During runoff and precipitation events the maintenance activities may need to be intensified in order to prevent possible erosion control structures failing and potentially increasing resource degradation.

Effectiveness:
Properly designed, installed and maintained, erosion and sediment control structures will effectively reduce the transport of sediments, minimize erosion and the degradation of water resources and reduce negative impacts to natural resources (i.e. vegetation, wildlife, etc.).

4.1.4 Revegetation:

Revegetation practices will be conducted in accordance with SDAR 74:29:07:06 and the methods outlined in the SD DENR mining permit. In order to help reduce wind and water erosion, topsoil stockpiles and other various disturbances in the well field area will be seeded throughout the PAA. Per SDAR 74:29:07:06, the seed mix will be chosen to be compatible with the post-production land use. The local conservation district, landowners and the SD DENR will be consulted when selecting the seed mix. The licensee will consult with local conservation district to develop and implement a site specific noxious weed control plan (ARSD 74:29:07:15).

Definition:
Seeding practices include a variety of techniques which result in the sowing or planting of seeds. Common practices include:

- Broadcast seeding (hand or mechanical)
- Drill seeding
- Aerial seeding
- Hydroseeding

Purpose:
To provide soil stabilization through vegetative cover; Objectives related to revegetation include but are not limited to:

- Reduction of impact from rain
- Reduction of impact from surface water flow velocity
- Reduction of erosion from wind and water
- Enhancement of the natural environment and aesthetics

Applicability:
Revegetation is applicable to most surface disturbance requiring reclamation. Mechanically stabilized slopes are candidates for re vegetating. Drilling seeding is usually limited to a 3:1 slope or less. Hydroseeding is successful on flat or steep slope situations. Broadcast method is less expensive and requires about twice the seed amount as drilling. Aerial technique is typically utilized over large areas with little or no ground access.

Planning Criteria:
As stated above, seed selection will be based upon site specific land use and qualified professionals will be consulted. Considerations taken when planning the revegetation will consist of:

- Typical economics
- Topography of site
- Application method appropriate for type of vegetation being established
- Slope stabilization (if necessary before re vegetation efforts begin)
- Supplemental techniques and/or material necessary for establishment of seed (mulch, netting, matting, chemicals)
- Water retention methods and planting season
- Prevention of wash out

Methods and Materials:
Qualified vegetation or reclamation specialists will be consulted regarding seed selection, seeding rates, season, and application of mulch to ensure the most successful re vegetation efforts.

Broadcast seeding (hand or mechanical):
Broadcast seeding can be accomplished by hand held seeders or a mechanically driven seeder typically mounted on a tractor or ATV vehicle. The seed mix is placed in a hopper, adjustments are made for the size of the seed and rate of application and the seeder is operated by a hand crank or motor while walking or driving over the areas to be seeded. Broadcast seeding typically requires twice the amount of seed to cover the same given area as a drill seeder due to wind drift, wildlife consumption and lack of good soil to seed contact.

Drill seeding:
Drill seeding requires the use of a Range drill or equivalent depending on the condition of the site. Drill seeders are pulled behind a tractor or bulldozer and actually place the seed to a pre-determined depth. The seed is then covered by the drill mechanism or a chain drag is utilized to cover the seed behind the drill.

Aerial seeding:
Aerial seeding is conducted by helicopter or fixed wing aircraft and can cover large areas of inaccessible terrain. It is the most efficient method for large disturbance areas such as forest or rangeland fires. Germination success is usually low given wind drift, soil conditions, and poor seed to soil contact, but application timing can greatly improve success.

Hydroseeding:
The wood fiber and water mixture are well agitated in a large tank and then blown through a hose and nozzle by compressed air. The apparatus is typically truck or trailer mounted and has sufficient capacity to complete several acres at a time. Mulch application rates and/or seeding rates depend upon the site specifics of the project area and the project goals.

Maintenance:
Regular inspection of re seeded areas and re application if necessary will be carried out to ensure a successful re vegetation project. The treated areas will be protected from foot or vehicular traffic until the vegetation is well established. This may require signs, fencing or some other type of barrier to prevent entrance.

Effectiveness:
With proper selection of appropriate seeding method(s), season, proper seed mixture, application rate and maintenance the revegetation effort(s) will result in the most successful and effective methods of soil stabilization and long term benefits to the designated land use.

Surface reclamation at the PAA will incorporate the following three major activities some of this will occur simultaneously:

- Radiological decommissioning and decontamination of buildings, process vessels and other structures, and/or affected areas
- Removal and reclamation of the CPP and SF, and auxiliary structures
- Reclamation of restored well fields including production and monitor well plugging and abandonment

4.1.5 Facility Decommissioning

Removal or Stabilization of Buildings, Structures and Support Facilities:

Due to the nature of ISL production, minimal and intermittent surface disturbance will be associated with the project, and will be mainly associated with the CPP, maintenance and office areas. All buildings and structures will be decontaminated to regulatory standards and demolished and trucked to an approved disposal facility. The solid materials include metals, building concrete, onsite soils, equipment, furniture, etc., which are present at, and/or used in, the licensed nuclear facility during routine operations. Release will not occur unless materials meet the release criteria outlined in 10 CFR Part 40, Appendix A. Baseline soils, vegetation, and radiological data will be used as a guide in evaluating the final reclamation.

Table 4.1-1 specifies the levels of decontamination that must be obtained for buildings, process vessels, ancillary structures, and affected areas prior to final reclamation to unrestricted release in accordance with NRC requirements, or the contaminated material must be removed to the appropriate disposal facilities. Decontamination may include acid, and water wash down of structures, and concrete. The resulting solvents will be disposed as byproduct material by disposal well, and/or evaporation. Equipment, which cannot be decontaminated, will be dismantled, and disposed of in a licensed disposal facility, or utilized at another licensed uranium facility. All uncontaminated foundations will be removed, or broken, and buried in place. All survey results will be documented and maintained on site or at the headquarters upon termination of license.

Table 4.1-1 NRC Acceptable Surface Contamination Levels[1]

Nuclide[a]	Removable [b,e,f] (dpm/100 cm^2)	Average [b,c,f] (dpm/100 cm^2)	Maximum [b,d,f] (dpm/100 cm^2)
UNat, U-235, U-238, and associated decay products	1000 a	5000 a	15000 a
Transuranics, Ra-226, Ra-228, Th-230, Th-228, Pa-231, Ac-227, I-125, and I-129	20	100	300
Th-nat, Th-232, Sr-90, Ra-223, Ra-224, U-232, I-126, I-133, and I-131	200	1000	3000
Beta-gamma emitters (nuclides with decay modes other than alpha emission or spontaneous fission) except Sr-90 and others noted above	1000 bg	5000 bg	15000 bg

a Where surface contamination by both alpha and beta-gamma emitting nuclide exists, the limits established for alpha and beta-gamma emitting nuclide
should apply independently.
b As used in this table, dpm means the rate of emission by radioactive material as determined by correcting the counts per minute observed by an appropriate detector for background, efficiency, and geometric factors associated with the instrumentation.
c Measurements of average contaminant should not be averaged over more than 1 m2 . For objects of less surface area, the average should be derived for each such object.
d The maximum contamination level applies to an area of not more than 100 cm2 .
e The amount of removable radioactive material per 100 cm2 of surface area should be determined by wiping that area with dry filter or soft absorbent paper, applying moderate pressure, and assessing the amount of radioactive material on the wipe with an appropriate instrument of known efficiency..
When removable contamination on objects of less surface area is determined, the pertinent levels should be reduced proportionally and the entire surface should be wiped.
f The average and maximum radiation levels associated with surface contamination resulting from beta- gamma emitters should not exceed0.2 millirad per hour (mrad/hr) at 1 cm and 1.0 mrad/hr at 1 cm, respectively, measured through not more than 7 mg/cm2 total absorber.
The external gamma exposure rate should not exceed 5 microroentgen per hour above background at 1 meter from the surface and for soil 10 microroentgen per hour, above background at 1 meter.
[1] Table obtained from Appendix U (NRC Acceptable Surface Contamination Levels) of U.S. Nuclear Regulatory Commission, Guidelines for Decontamination of Facilities and Equipment Prior to Release for Unrestricted Use of Termination of Licenses for Byproducts, Source, or Special Nuclear Material, April 1993.

Definition:
To mitigate surface disturbances associated with the construction of the CPP, office and maintenance buildings.

Purpose:
At the completion of the project, all disturbed lands will be returned to their pre-production land use of livestock grazing and wildlife habitat pursuant to ARSD 74:29:07:20 and 74:29:07:22, respectively.

Applicability:
The removal or stabilization of buildings, structures and support facilities are applicable to the achievement of meeting the objective of the surface reclamation effort of returning the disturbed land to equal or better condition than pre-production.

Planning Criteria:
Qualified professionals will be utilized in the planning which will result in the safe removal of structures and support facilities. Some of the criteria that will be evaluated before decommissioning and disposal begin is:

- The Establishment of Surface Contamination Limits
- Preliminary Radiological Surveys and Contamination Controls

- All Decommissioning Procedures in Accordance with the NRC license, Titles 10 and 49 of the CFR, ARSD 74:29:11:28, SDCL 45-6B-38, and other applicable regulatory requirements.

Methods and Materials:
The procedures for removing and disposing of structures and equipment include the establishment of surface contamination limits, preliminary radiological surveys of process building surfaces, equipment and piping systems; strategic cleanup and removal of process building materials and equipment, sorting materials according to contamination levels and salvageability, and preparing materials for transport and offsite (unrestricted) use or disposal. Although not mentioned hereafter, the procedures also apply to tools and other equipment, such as backhoes.

Removal of Process Building and Equipment:
Decommissioning for the CPP and auxiliary structures is dependent upon two key factors, market price and feed material. At which time Powertech has determined it is no longer economically viable to retain the CPP and auxiliary structures these structures will be decommissioned and decontaminated and the area will be released for unrestricted use. Prior to the release for unrestricted use, Powertech will submit verifying information that radionuclide concentrations meet the NRC release standards.

Facility decommissioning may be accomplished in two phases:

Phase I – Equipment that is not utilized in final groundwater restoration (including stability period) may be decontaminated (if surveys indicate decontamination is necessary), surveyed and released for unrestricted use.

Phase II – Plugging of wells and removal of the remaining equipment post final groundwater restoration completion and agency approval.

Powertech (USA) will develop plans for the strategic removal of process building(s) and equipment, based on inventory, the results of the radiological surveys, decontamination options and available methods, reuse/disposal pathways, and information obtained during the effort. To the extent possible, Powertech (USA) intends to decontaminate salvageable equipment for unrestricted release. Decontamination methods may include a combination of washing, high pressure sprays, or steam cleaning. Cleaned surfaces will be air-dried prior to radiological monitoring. The ALARA principle applies to decommissioning activities. As such, surface contamination will be reduced to levels as far below applicable limits as practical.
Powertech (USA) will document the results of radiological surveys for all building materials, systems, and equipment. These items will be sorted as follows:

- Salvageable and contaminated above release limits (not releasable but potentially disposable or transferrable)
- Salvageable and contaminated below release limits (releasable) for unrestricted use
- Not salvageable and contaminated above release limits (offsite disposal at a facility licensed to accept 11e.(2) byproduct material)
- Not salvageable and contaminated below release limits (offsite disposal at a permitted facility)

In the first case, the item may be transferred to another NRC or Agreement State licensee. If it cannot be transferred or decontaminated to be released for unrestricted use, it will be disposed of at a licensed disposal facility. In all cases, Powertech (USA) will strictly maintain an inventory of all process building and equipment and the results of radiological surveys.

4.1.5.1 Building Materials, Equipment and Piping to be Released for Unrestricted Use

Powertech (USA) will develop an approved standard operating procedure for release of items to unrestricted use and thoroughly document all items eligible for release to unrestricted use. To the extent possible, releasable items having a salvageable value will be sold on the industrial market. Releasable items having no net salvageable value will be sent to a municipal landfill.

4.1.5.2 Preparation for Disposal at a Licensed Facility

All materials and plant equipment unsuitable for unrestricted release will be prepared for offsite disposal at a licensed facility. Building materials, tools, and equipment destined for offsite disposal will be prepared for transportation and disposal in accordance with 49 CFR and other applicable requirements.

4.1.5.3 Waste Transportation and Disposal

Waste transportation will be performed in accordance with 49 CFR and all other applicable regulations. Offsite shipments will be properly prepared, in terms of packaging, marking and labeling, dose rate measurements, shipping papers, and emergency contact information. Offsite disposal will be conducted in accordance with disposal facility licensing requirements, including waste characterization and profiling.

Maintenance:
During decommissioning efforts qualified personnel trained in environmental, health, safety and radiation safety will be present on site to assure pre and post surveys are conducted according to procedure and properly documented. Personnel responsible for decommissioning activities will monitor removal of contaminated materials to ensure decommissioning efforts are carried out to the letter of the law and company procedures.

Effectiveness:
Gamma surveys will be performed over the extents of the affected lands post decommissioning. The surveys will be used, in conjunction with soil sampling and analysis to verify cleanup meets the site cleanup criteria.

4.1.5.4 Radiological Survey

Prior to release for unrestricted use radiation surveys will be performed in all areas of well fields, surface impoundments, and process buildings. These areas will also be analyzed for radium content via soil sampling. Final surveys will be performed for confirmation of cleanup standards. All equipment designated for unrestricted release will be surveyed and records of all surveys will be maintained.

4.1.5.5 Quality Assurance Program

Powertech (USA) will prepare a QAPP that establishes the quality assurance and control measures for field measurement, sample collection, and laboratory analysis for all decommissioning activities. The QAPP will also establish performance criteria for field and laboratory data precision, accuracy, completeness, and representativeness. The QAPP will contain recommendations in NRC Regulatory Guide 8.15, Quality Assurance for Radiological Monitoring Programs (Inception through Normal Operations to License Termination)-Effluent Streams and the Environment (NRC, 2007).

4.1.5.6 Environmental Monitoring

Monitoring of air quality, water quality vegetation and soils will be conducted throughout the duration of the project activities and upon termination of license in order to comply with all environmental release criteria for termination of the licensed facility. Environmental information will be submitted to the NRC and other appropriate agencies on an annual basis and a termination of licensing meeting will be conducted with regulators in order to comply with federal and state decommissioning requirements before releasing the site for unrestricted use.

Data submitted to agencies will include:

- Soil sample and analysis
- Decommissioning equipment and building smear samples and analysis
- Gamma Survey results and maps
- Environmental monitoring results

4.2 Groundwater Restoration and Schedule

After active uranium recovery operations cease, Powertech (USA) intends to complete site decommissioning and reclamation, including groundwater restoration with the ultimate goal of releasing the Proposed Action site for unrestricted use. The groundwater restoration method proposed for the Dewey-Burdock Project is based on the successful programs implemented by other projects such as the Lamprecht, Cogema Irigaray Restoration Project or Crow Butte Resources, Inc., which have received regulatory approval from NRC for successfully restoring groundwater to previous class of use. The groundwater restoration methods consist of permeate injection using the reverse osmosis process and aquifer recirculation.

In each well field, production activities will proceed until such time as the uranium concentration in the pregnant solution has declined to an uneconomic recovery level. After production ceases, Powertech (USA) will be restoring the groundwater consistent with baseline and in accordance with 10 CFR Part 40 Appendix A, Criterion 5(b) (5) and ARSD 74:29:07:08. Reclamation of surface disturbances will occur after completion of restoration activities in a well field and will continue in the same manner after additional well fields are developed, produced and restored. Therefore, at any time there may be well fields in three different stages of the process: wellfields in production, well fields undergoing groundwater restoration, and well fields undergoing surface reclamation. Additionally, there also may be some small areas indirectly related to these process phases that are held unreclaimed for short periods of time (e.g., storage of top soil). This proposed operational and reclamation plan ensures minimal potential environmental impacts.

4.2.1 General Groundwater Restoration

Definition:
To bring back water quality to a former use or condition.

Purpose:
After production ceases, Powertech (USA) will be restoring the groundwater consistent with baseline and in accordance with 10 CFR Part 40 Appendix A, Criterion 5(b) (5); with the ultimate goal of releasing the Proposed Action site for unrestricted release.

Applicability:
Groundwater restoration is applicable to all ISL operations in order to restore the quality of water found within each mine unit within the exempted aquifer prior to mining. The primary goal of groundwater restoration at the site will be to return groundwater quality within the production zone of a well field consistent with pre-operational baseline water quality conditions or to standards consistent with NRC's application of Criterion 5B(5) of Appendix A to 10 CFR Part 40 and ARSD 74:29:11:06. In the event that Powertech (USA) is unable to restore such groundwater consistent with preoperational baseline water quality conditions, the secondary goal would be to return water quality to its pre-operational livestock watering and agricultural class of use.

Planning Criteria:

Prior to operation, the baseline groundwater quality will be determined through the sampling and analysis of water quality indicator constituents in wells screened in the mineralized zone(s) across each well field. Based on statistical analysis of the data following ASTM Standard D 6312 (ASTM, 2001) to determine the baseline range of statistical variability of an indicator constituent; target restoration goals (TRG) will be established. Powertech (USA) will attempt to meet the TRG established for each constituent during the groundwater restoration process. Table 4.2-1 provided below, lists the baseline water quality parameters and the analytical methods that will be used for establishing groundwater TRG:

Table 4.2-1 Baseline Water Quality Parameters

Test Analyte/Parameter	Units	Method
BULK PROPERTIES		
pH	pH Units	A4500-H B
Total Dissolved Solids (TDS)	mg/L	A1030 E1, A2540 C
Conductivity	µmhos/cm	A2510B
CATIONS/ANIONS		
Chloride	mg/L	E300.0
Sulfate	mg/L	E300.0
Total Alkalinity (as CaCO3)	mg/L	A2320 B
TRACE METALS		
Arsenic, As	mg/L	E200.8
Iron, Fe	mg/L	E200.7
Lead, Pb	mg/L	E200.8
Manganese, Mn	mg/L	E200.8
Strontium	mg/L	E200.8
Uranium, U	mg/L	E200.8
Vanadium	mg/L	E200.7, E200.8
RADIONUCLIDES		
Gross Alpha=Alpha Particles	pCi/L	E900.0
Gross Beta=Beta Particles and Photons	mRem/Year	E900.0
Radium-226	pCi/L	E903.0
Radon-222	pCi/L	D5072-92

Table adapted from USNRC (2008) *Generic Environmental Impact Statement for In-Situ Leach Uranium Milling Facilities-Draft Report for Comment*, NUREG-1910, July 2008. Notes: mg/L = milligrams per liter; µmhos/cm = micromhos per centimeter; PCi/L = picocuries per liter. All metals analyses are for dissolved metals.

Powertech (USA) will consult with DENR concerning the specific groundwater suite of constituents prior to well field baseline evaluation. In the event that secondary groundwater restoration standards may need to be considered for specific constituents, Powertech (USA) will provide data and justification for restoring groundwater water quality to pre-operational class of use.

Methods and Materials:
There are several methods available to operators to utilize and often times these methods are combined to assure effectiveness based upon the geochemistry and hydrology of the individual well field undergoing restoration. The main groundwater restoration techniques utilized by the industry include:

- Groundwater Transfer
- Groundwater Sweep
- Reverse Osmosis, Permeate Injection, and Recirculation

Aquifer restoration criteria are determined on a site-specific, well field-by-well field basis. NRC's restoration standards are found in Appendix A to 10 CFR 24 Part 40.

Aquifer restoration programs typically use a combination of methods including: (1) groundwater transfer, (2) groundwater sweep, (3) reverse osmosis with permeate injection, (4) groundwater recirculation, and (5) stabilization monitoring (Energy Information Administration, 1995; Mackin, et al., 2001; Davis and Curtis, 2007).

Groundwater Transfer:
The groundwater transfer method replaces affected groundwater with baseline quality water from a well field coming on line for ISL. This involves transferring groundwater between a mined out wellfield and the next wellfield being brought on line for ISL operations or within a separate area of the same wellfield that may be in an advanced phase of restoration (NRC, 2006). The groundwater resulting from this method is therefore blended until dissolved constituents are similar in concentration. Groundwater transfer does not typically generate liquid effluents.

Groundwater Sweep:
The groundwater sweep method removes affected groundwater from a mined out well field by pumping. The pumping allows unaffected groundwater contained within the aquifer to flow into the mined out portion of the aquifer. The water may be supplemented with makeup water from the Madison formation to increase the restoration rate. The affected groundwater pumped from the well field is routed to the IX recovery in order to remove the uranium. The process water is routed to a radium removal system where the radium is precipitated and settled before disposal via land application in accordance with a groundwater discharge permit from DENR or deep well injection in accordance with a UIC permit.

Reverse Osmosis, Permeate Injection, and Recirculation:
During permeate injection and recirculation, uranium, if in sufficient concentration in the groundwater is removed by passing the water through an uranium scavenging ion exchange circuit, as during operations. After that, other chemical constituents in the groundwater are removed, as necessary, by passing the groundwater through a reverse osmosis system consisting of pressurized, semi-permeable membranes.

The reverse osmosis process yields two fluids: clean water (permeate: about 70 percent) and water with concentrated ions (brine: about 30 percent). The reject (brine solution) can be disposed directly in an evaporation pond or via a deep well injection in accordance with the discharge limits in the UIC permit. If the reject is sent directly to an evaporation pond or a deep disposal well, the net withdrawal from the aquifer could be about 30 percent of the pumping rate (tens of gallons per minute).

Alternatively, a brine concentrator can be used to treat the reject. The brine concentrator heats and evaporates the water, concentrating the brine, which then contains precipitated solids in the form of common salts. The brine concentration process typically results in about one part briny slurry and salts to 300 parts purified water. The purified water can be reintroduced into the aquifer and thus the net withdrawal from the aquifer would be only a small percentage of the recirculation rate. The briny slurry is disposed in an evaporation pond or via deep well injection.

Groundwater Treatment:
The groundwater treatment method of restoration is similar to the injection sweep method in that uncontaminated water is injected in perimeter wells. In this method of restoration, the groundwater removed during restoration is treated by reverse osmosis to divide it into a permeate stream containing most of the water, but about 10 percent of the dissolved solids in the restoration flow, and a reject stream containing a relatively small portion of the volumetric flow, but a large fraction of the dissolved solids. The permeate stream is relatively uncontaminated and is a suitable source for a portion of the uncontaminated water injected at the perimeter of the well field. In addition to this permeate recycle; a make-up stream of fresh water from an outside well will be required, as described in the injection sweep method, but requiring a much smaller amount of this water from an outside source. The reject stream is then disposed of in a suitable deep disposal well, as described in Section 4.3.3.

4.2.2 Deep Disposal Well Option

Powertech has determined that Class I (Hazardous Waste) deep injection wells are prohibited within South Dakota, and in fact, the probability of discovering a horizon that has no possibility of a USDW horizon beneath the injection zone is remote. The nearest Class I disposal well site associated with a licensed facility is at Crowe Butte Resources in Nebraska, approximately 97 miles from the proposed action.

Therefore, Powertech intends to apply for a Class V (Non Hazardous) deep injection permit for disposal of liquid wastes generated from the project through a permitting process with USEPA. The permit would encompass the proposed action permit boundary in an area type permit application. It is proposed that two wells will be installed; one near the Dewey SF site and one near the Burdock CPP site. Ideally these will be located within approximately ¼ mile of each plant site.

The proposed locations of the wells are presented in Exhibit 1.1-1. Regional geology and measurements of water character value within the Minnelusa horizon of Permian Age shows that the horizon has sufficient permeability and sufficiently low water quality that deep well injection would be viable for disposal of process liquid waste with removal of hazardous constituents (Figure 4.2-1 Regional TDS Distribution). Existing water quality data from oil gas exploration and development in the area is presented in Figure 4.2-1. Several analyses indicate TDS concentrations above 10,000 ppm meeting the UIC program criteria for suitability for injection.

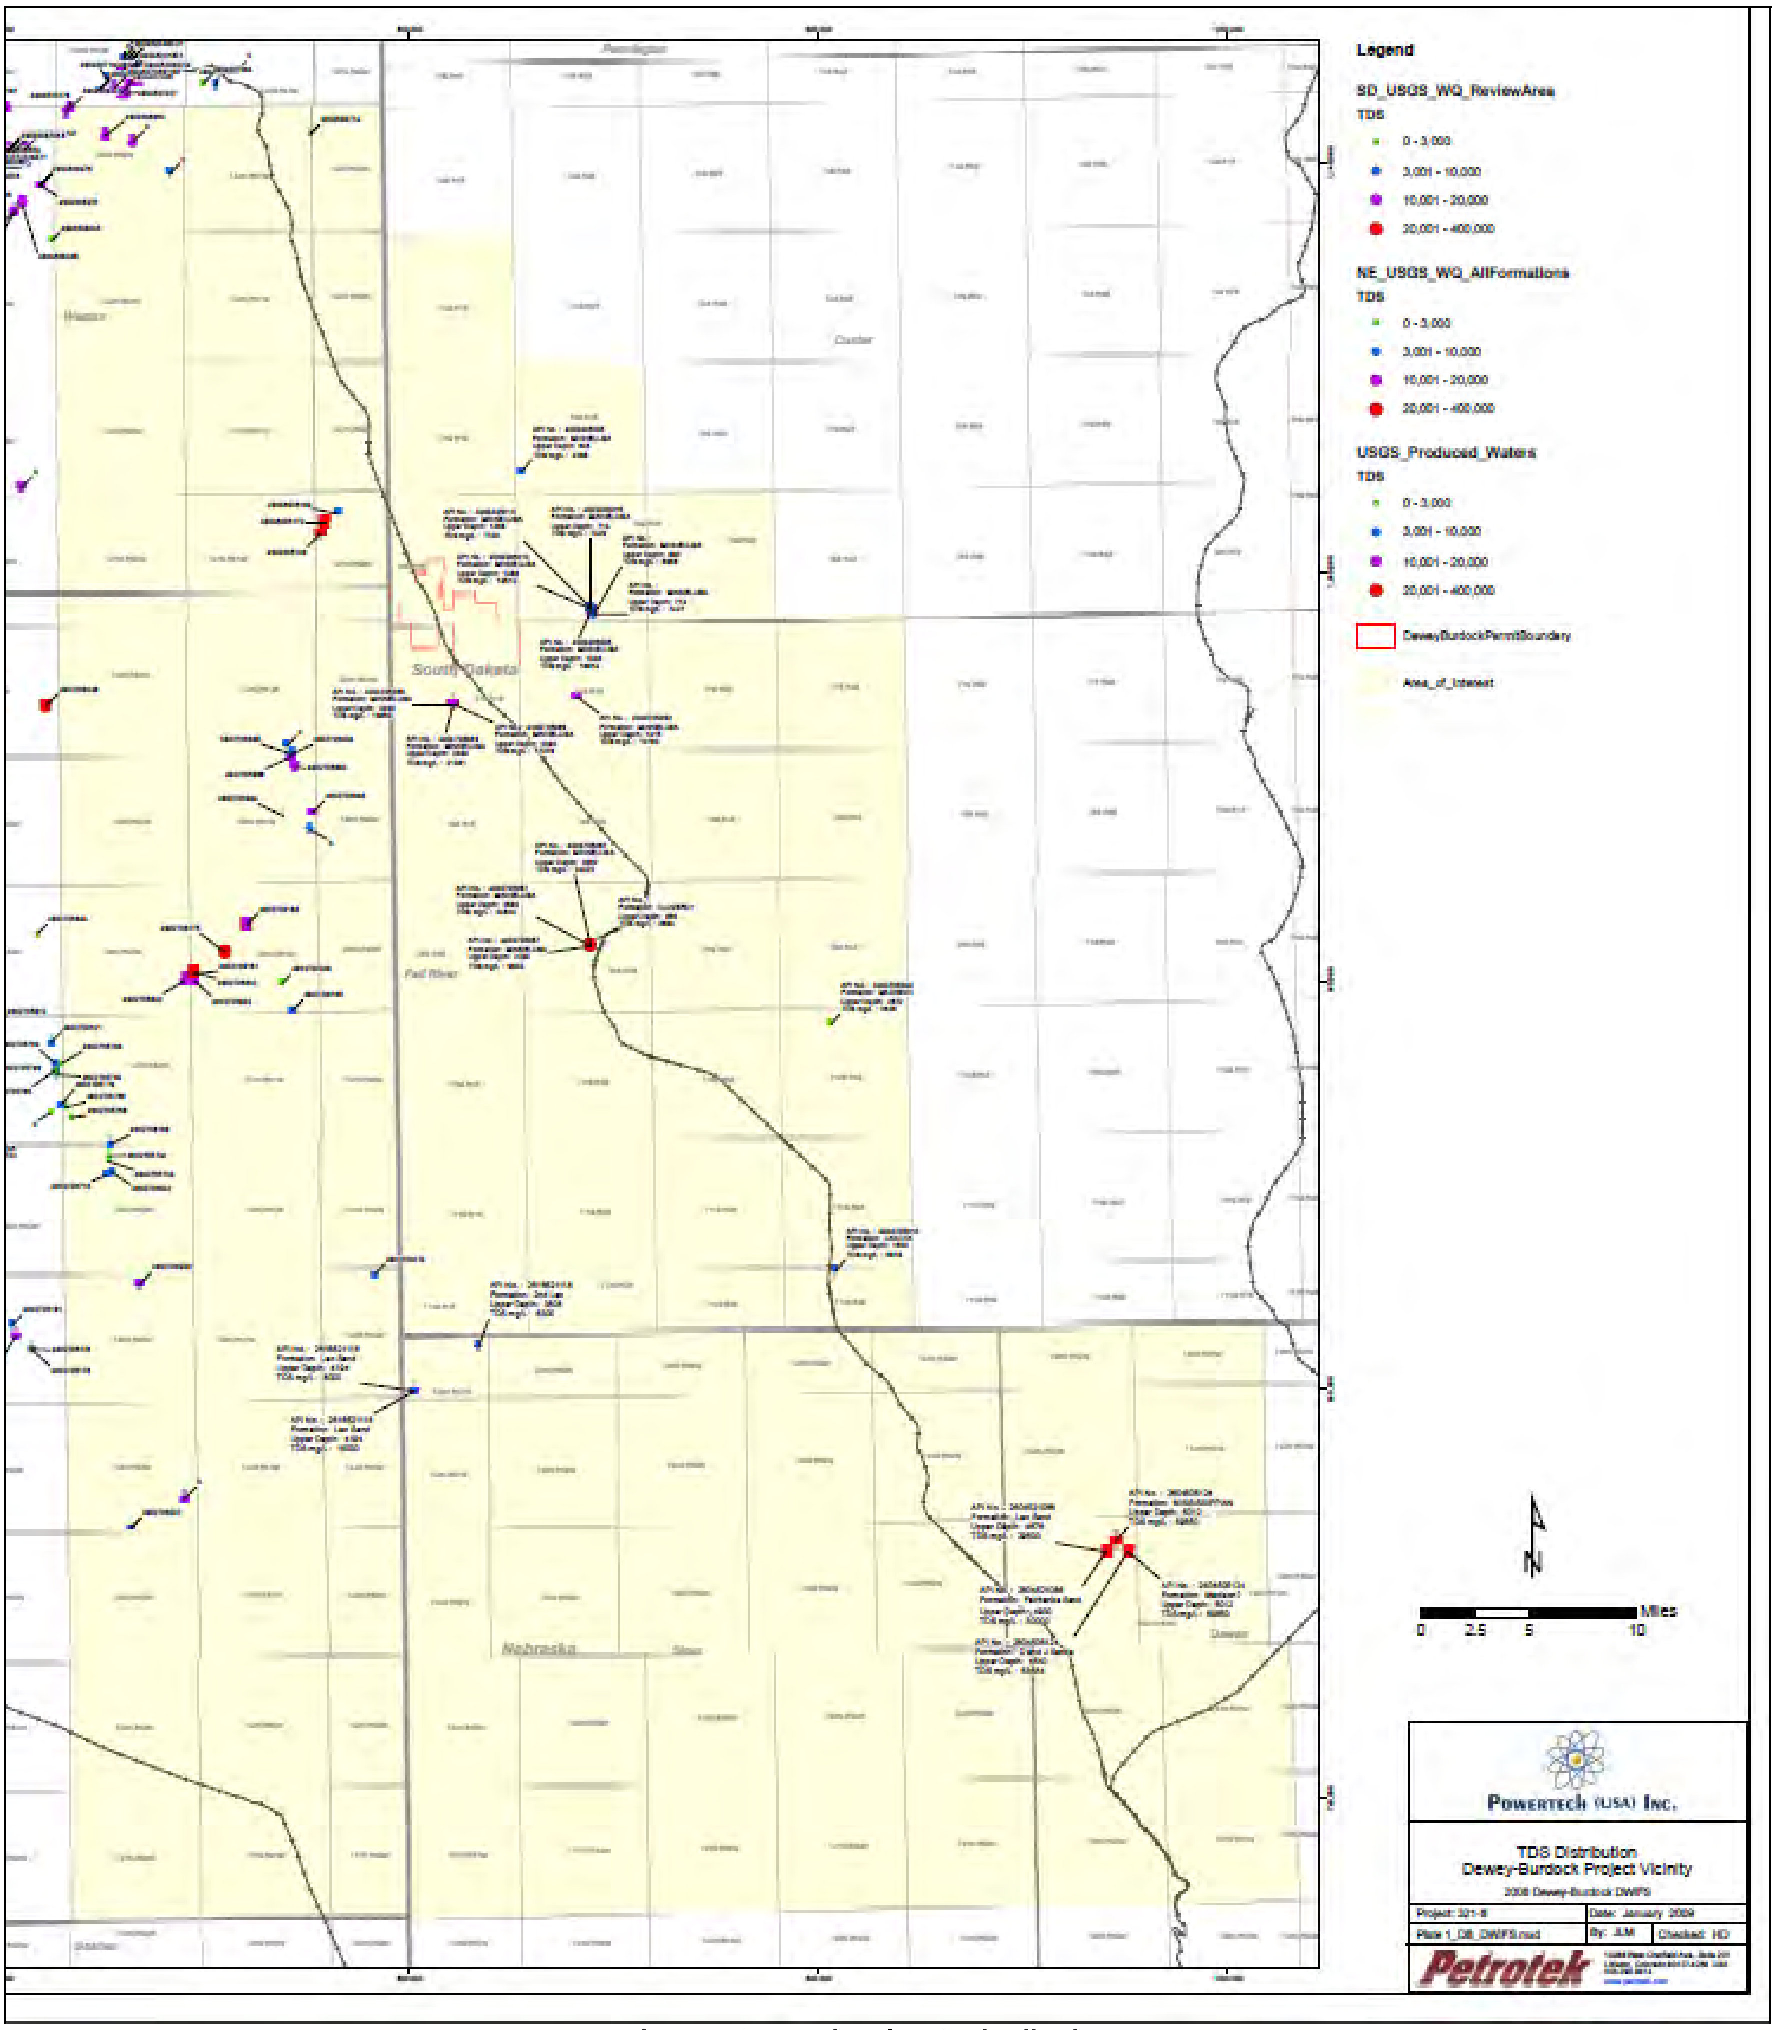

Figure 4.2-1 Regional TDS Distribution

The injection zone for each well is intended to be determined from deep exploratory drilling and collection of fluid sample data from multiple injection target zones. The expected targeted zones consist of the Minnelusa formation or deeper. Formations in consideration are the Minnelusa, Leo Sandstone, Madison, and Deadwood. Regional cross sections in general, can be viewed on the cross section index map, Figure 4.2-2. The regional cross sections, A-A' and B-B' are depicted in Figures 4.2-3 and 4.2-4, which include existing geophysical data which typically ends in the lower portion of the Leo formation and upper Madison formation. Current data does not include the Deadwood formation which is a potential target below the Madison formation. Results of the exploratory sampling prior to installing the wells, will allow proper selection location of the injection activity based upon the determination of water quality throughout all of these formations.

POWERTECH (USA) INC.

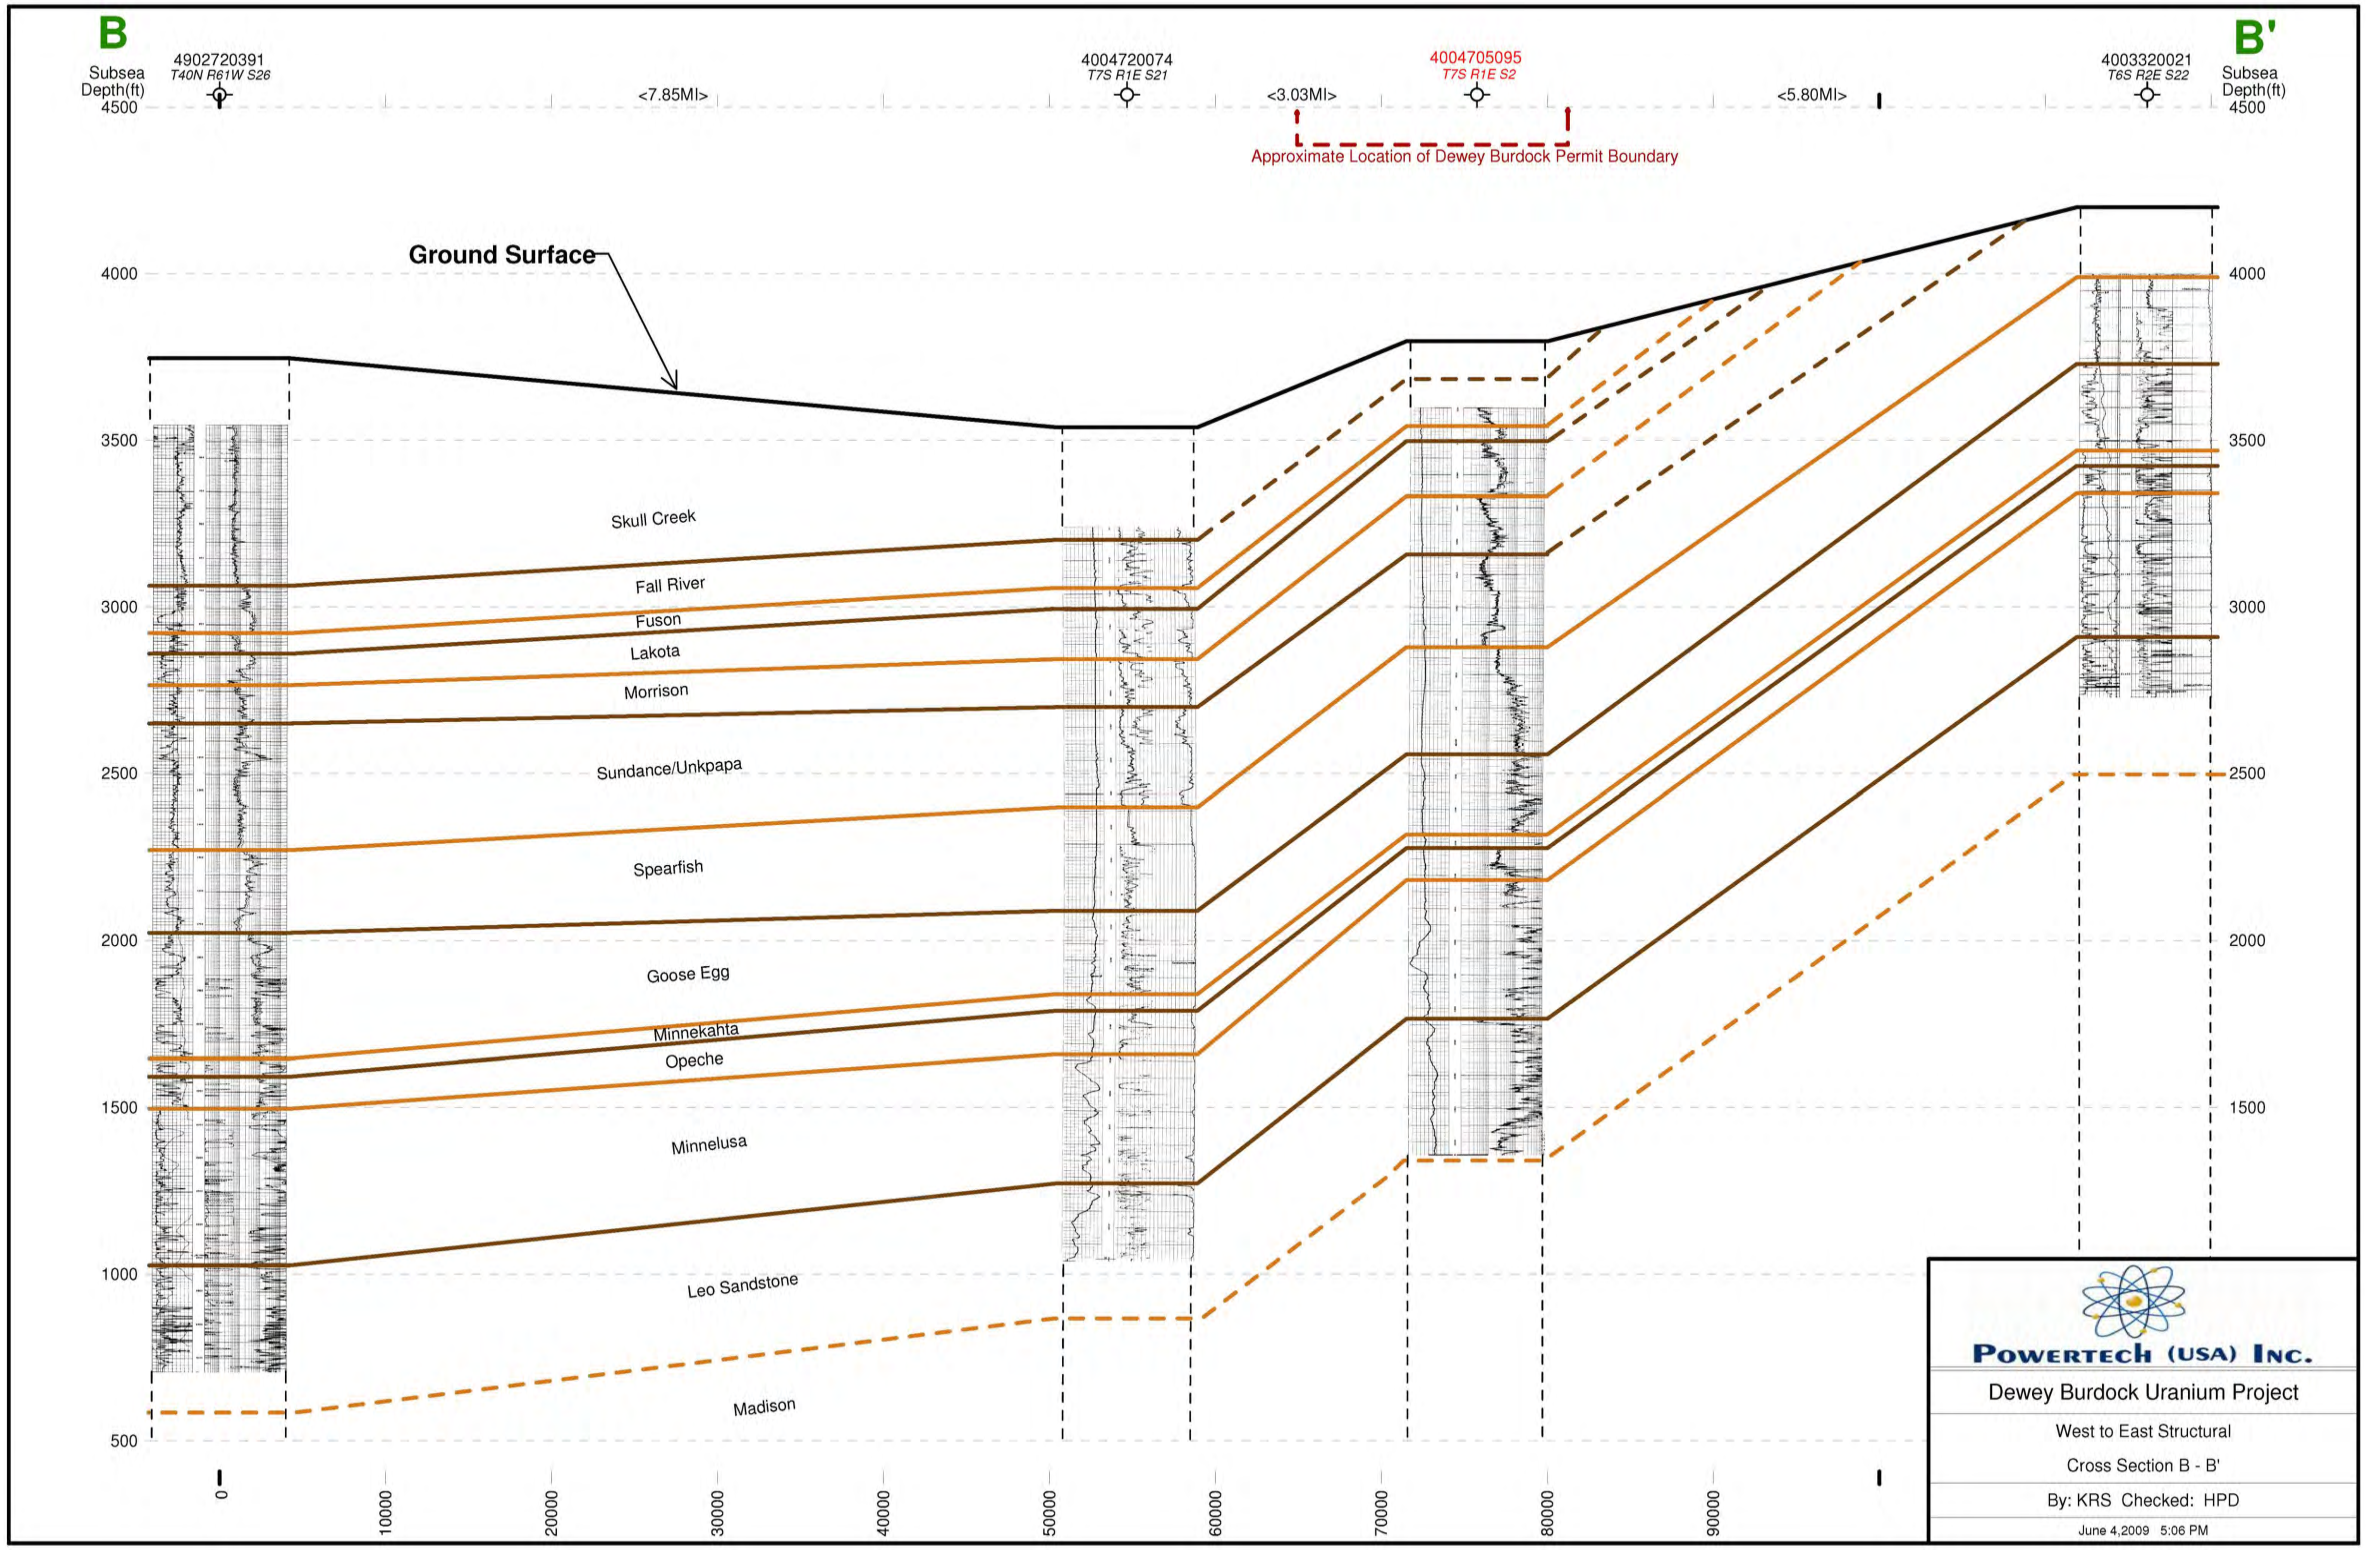

Figure 4.2-4 Regional Cross Section Index B-B'

The proposed ponds for extraction of radium are shown on Exhibits 1.1-1 and 1.1-2 as Radium Settling Ponds. Should water quality standards and the geological subsurface characteristics meet the UIC criteria for disposal of all constituents within the waste water, radium settling ponds would not be utilized.

Waste will consist primarily of the bleed streams from production and restoration operations. Typically these streams will be concentrated by reverse osmosis to minimize waste volume. In addition, these streams will also be combined with lesser amount of fluid generated by the central processing plant and consisting of waste brine from the elution process. The combined waste stream will fall under the classification of non-hazardous, 11e.(2) waste suitable for deep injection well disposal under EPA Class V regulations.

4.2.3 Disposal Well Design

Figures 4.2-3 and 4.2-4 depict the section that will be proposed for permitting. It is clear from these cross sections that the depth and character of the horizon is of sufficient thickness to support the application for a Class V permit.

Well construction will meet EPA requirements; the general construction details are described in Figure 4.2-5. The general description of the design consists of a cemented steel casing from total depth to surface, an internal tubing string, and a packer sealing the casing just above the point of injection. Injection is performed through the tubing and through the packer to the perforations below. The annulus pressure between the tubing and well casing will be continuously monitored to prevent any potential leakage of the injected waste fluid into overlying formations. Operational procedures also include a mechanical integrity testing of the casing to additionally insure against well leakage, with results submitted to all appropriate agencies for approval of injection of non-hazardous waste water with appropriate controls.

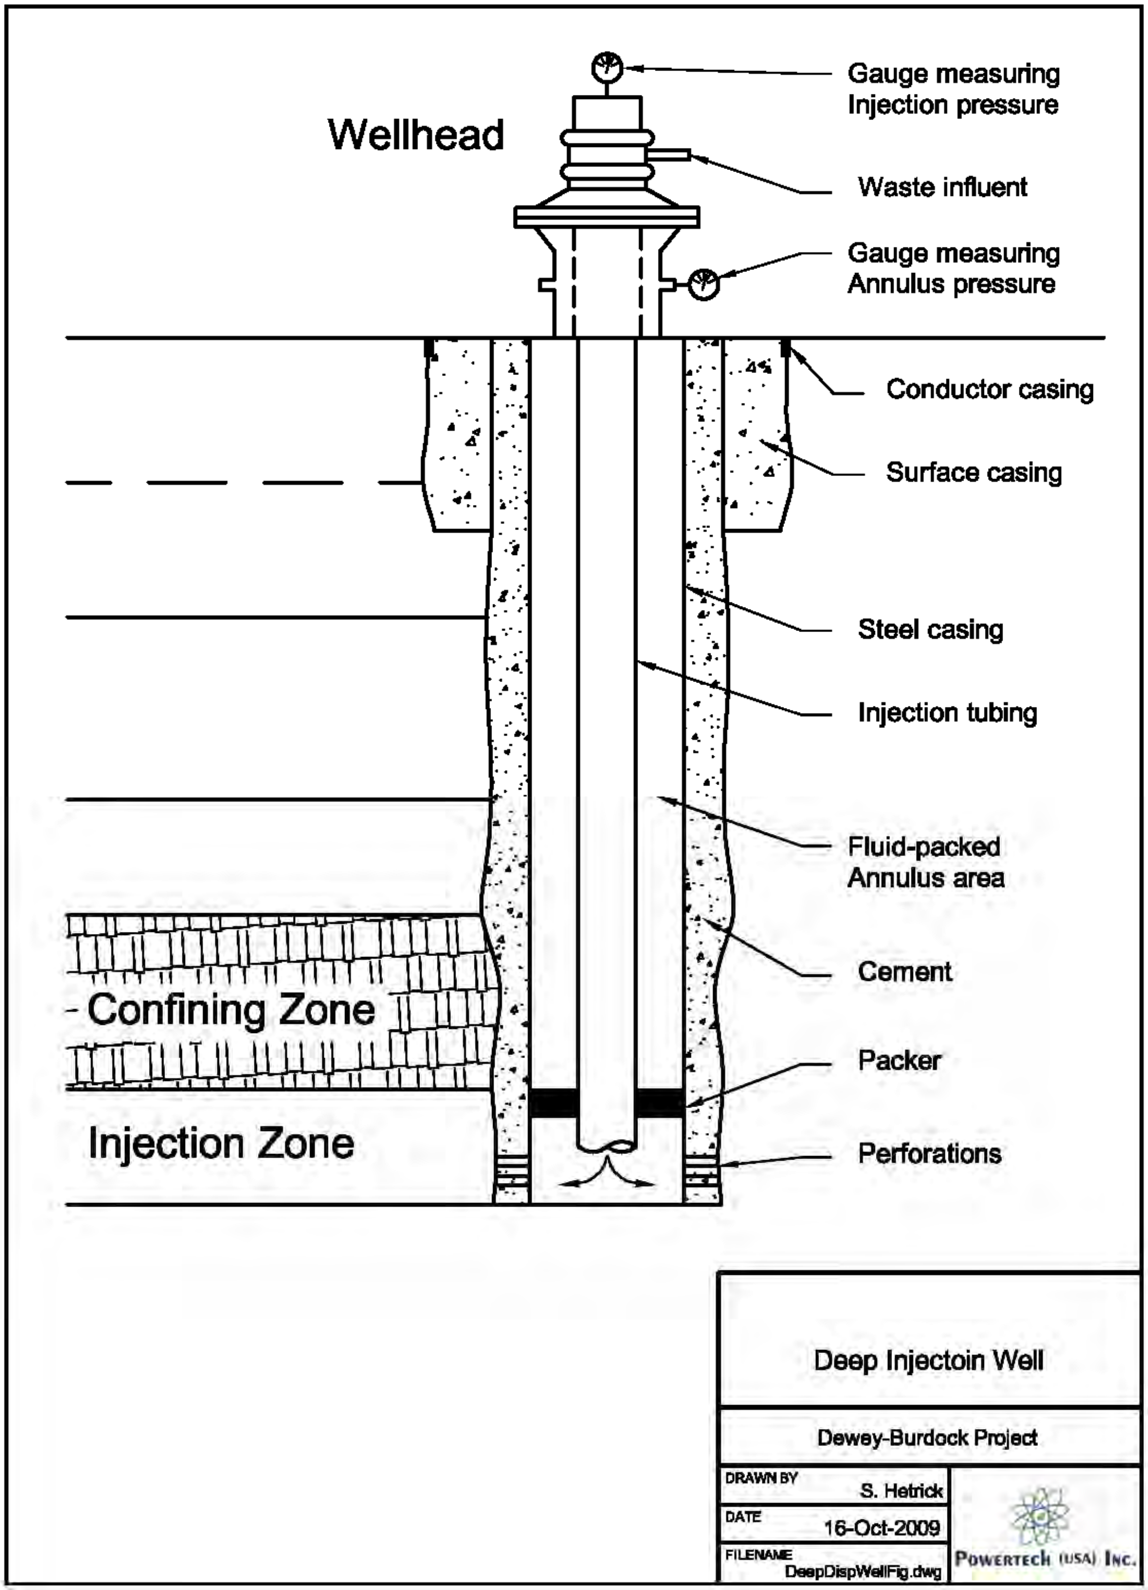

Figure 4.2-5 Deep Injection Well

4.2.4 Land Application Option

Exhibit 1.1-1 describes the proposed location of the Radium Settling Ponds that would be used prior to land application. In addition to the Radium Settling Ponds, wastewater holding ponds would be necessary for land application due to the lower evaporation rate in winter time. Powertech proposes the use of irrigation pivots to apply non hazardous waste water that meets the effluent discharge standards to the surface in order to grow grasses for cattle forage. This method was used regularly at Hobson, Mount Lucas and Highlands with no deleterious effect on the environment.

4.3 Pond Design

It is proposed that depending on the method of disposal ultimately selected, that all final data and design of as-built ponds will be submitted to the NRC and all appropriate agencies. The complete package will include design under the strictest engineering standards and will be designed and signed off by certified professional engineers.

Revised pond and water application designs for the land application option and pond designs for the deep well disposal option are presented in the Pond Design Report provided in Appendix 4.3-A. These designs have been completed following NRC Regulatory Guide 3.11-Rev. 1, NUREG 1569, 10 CFR Part 40, Appendix A, Criterion 5 and State of South Dakota Administrative Rule 74:29:11:23. A summary of the designs for both liquid waste disposal options is provided below.

4.3.1 Land Application Ponds

The land application option includes six categories of ponds:

- Radium settling ponds containing bleed and restoration water and used to settle radium out of solution.
- Outlet ponds used to intercept treated water from the radium settling ponds and to store storm water falling on the radium settling ponds.
- Storage ponds used to store treated water during the non-irrigation season.
- A central plant pond containing brine produced at the Burdock Plant site.
- A spare pond used for emergency containment should the radium settling or central plant ponds fail.
- A spare storage pond used for emergency containment should any of the storage ponds fail or portions of the land application system become temporarily inoperable.

The design of the land application ponds includes the following:

- Two radium settling ponds, one each at the Dewey and Burdock sites, having a storage capacity of 39.4 acre-ft each.
- Two outlet ponds, one each at the Dewey and Burdock sites, having a storage capacity of 4.9 acre-ft each.
- Two sets of storage ponds:
  - A system of four ponds constructed at the Dewey Site each having a storage capacity of 63.8 acre-ft.
  - A system of four ponds constructed at the Burdock Site each having a capacity of 63.8 acre-ft.
- Two spare storage ponds, one each at Dewey and Burdock sites having a storage capacity of 63.8 acre-ft.
- A central plant pond at the Burdock Site having a capacity of 36.2 acre-ft.

- Two spare ponds, one each at Dewey and Burdock sites having a capacity of 39.4 acre-ft.

4.3.2 Deep Disposal Well Ponds

The deep well disposal option includes five categories of ponds:

- Radium settling ponds, containing bleed water and restoration water and used to settle radium out of solution.
- Outlet ponds used to intercept treated water from the radium settling ponds and to store storm water falling on the radium settling ponds.
- A surge pond, containing water that has been treated and which is to be pumped to the disposal wells.
- A spare pond used for emergency containment should a liner on any of the ponds fail.
- A central plant pond containing brine produced at the Burdock Plant Site.

The design of the deep disposal well ponds includes the following:

- Two radium settling ponds, one each at the Dewey and Burdock sites having a storage capacity of 15.9 acre-ft each.
- Two outlet ponds, one each at the Dewey and Burdock sites having a storage capacity of 5.1 acre-ft each.
- Two surge ponds, one each at the Dewey and Burdock sites having a storage capacity of 8.4 acre-ft each.
- A central plant pond at the Burdock site having a capacity of 15.9 acre-ft.
- Two spare ponds, one each at the Dewey and Burdock sites having a capacity of 15.9 acre-ft.

All ponds have been designed to store water reporting to them while maintaining 3 feet of freeboard. The geometry and storage characteristics of the radium settling ponds have also been checked to verify that they will allow the efficient removal of radium from solution.

The radium settling, spare and central plant ponds will be provided with the following lining system:

- An 80-mil-HDPE primary liner
- A 60-mil-HDPE secondary liner
- A 1-ft-thick clay liner below the secondary liner
- A geonet drainage layer sandwiched between the primary and secondary HDPE liners
- A leak detection sump and access port system

All other ponds will contain treated water that is either to be used for land application or deep well disposal. These ponds will include a single 40-mil-HDPE liner underlain by a 1-ft-thick clay liner.

The results of the stability analyses calculated for the embankments using three different methods of analysis: (1) Bishop Method, (2) Janbu Method, and (3) Morgenstern-Price Method, indicate that the slopes are stable under both static and MCE seismic loading conditions.

The wastewater systems, deep well disposal and land application descriptions are discussed in further detail in Appendix 4.3-A (Pond Design Report, Land Application++ Report).

4.3.3 How Groundwater Restoration Methods are Dependent upon Disposal Methods

For ISL operations, a common commercial groundwater restoration program consists of a restoration stage and a monitoring stage. During restoration, groundwater will continue to be pumped from the well field, using a subset of wells that, during the production phase, functioned as either injection or production wells. The groundwater produced by these restoration wells will contain uranium and other constituents released during uranium production as well as residual lixiviant. Initial concentrations of these substances will be similar to those seen during production, but will decline gradually throughout the groundwater treatment process and further via the natural restoration process (NUREG/CR-3136, 1983). Water that is removed is first passed through an IX system to remove any available uranium.

Following IX, the groundwater will be treated by reverse osmosis to concentrate contaminants into a reject brine stream that is then injected into a Class V disposal wells. An alternate disposal method of treatment to remove contaminants, followed by storage and land application to produce an agricultural crop is also presented.

The specific method of groundwater restoration selected for the Dewey-Burdock project will depend on which option; deep well injection or treatment and land application, or combination thereof, as described in Section 4.2, is utilized for disposition of the wastewater from the restoration well fields.

The stability monitoring stage includes a period in which the indicator parameters identified in Table 4.1-1 are monitored in order to establish successful restoration consistent with NRC requirements.

Effectiveness:
With proper water quality evaluations of each individual well field, a thorough understanding of the hydrological characteristics and geochemistry of each well field and the use of qualified personnel that understand the processes utilized for groundwater restoration, the ultimate goal of releasing the exempted aquifer for unrestricted prior use will be accomplished.

The groundwater restoration methods described in this application have been successfully applied at other uranium ISL facilities in the US, including Irigaray/Christensen Ranch in Wyoming and Crow Butte in Nebraska.

Powertech (USA) will consult with DENR concerning the specific groundwater suite of constituents prior to well field baseline evaluation. In the event that secondary groundwater restoration standards may need to be considered for specific constituents, Powertech (USA) will provide data and justification for restoring groundwater water quality to pre-operational class of use.

4.3.4 Estimate of Post-Production Groundwater Quality

In order to estimate post-production water quality from ISL operations at the site, Powertech (USA) has reviewed operational restoration water quality data from six ISL operations in the western United States. These sites include:

- Irigaray/Christensen Ranch (Wyoming)
- Crownpoint (New Mexico)
- Crow Butte (Nebraska)
- Bison Basin (Wyoming)
- Smith Ranch/Highland (Wyoming)
- Ruth (Wyoming)

Based on this review, the Crow Butte site was selected for the estimate because of the proximity and similar geologic conditions to the project site, available water quality data, reasonable pore volume estimates to achieve restoration and overall restoration success. The water quality data for the Crow Butte site is extensive with baseline, post-production, post-restoration, and stabilization period data. Baseline water quality, post-production water quality, post-restoration average water quality and stabilization period average water quality data are provided in Table 4.3-1 for the Crow Butte Mine Unit No.1. Powertech (USA) may expect similar baseline and post-production water quality results at the project site.

Table 4.3-1 Crow Butte Post Mining Water Quality Data Summary

Parameter	Baseline Water Quality	Post-Mining Water Quality	Post-Restoration Average Water Quality	Stabilization Period Average Water Quality
BULK PROPERTIES				
Specific Cond.	1947	5752	1620	1787
pH	8.5	7.35	7.95	8.18
TDS	1170.2	3728	967	1094
CATIONS/ANIONS				
Alkalinity	293	875	321	347
Chloride	204	583	124	139
Sulfate	356.2	1128	287	331
TRACE METALS				
Manganese	0.11	0.075	0.01	0.02
Arsenic	0.002	0.021	0.024	0.017
Iron	0.044	0.078	<0.05	0.09
Lead	0.031	<0.05	<0.05	<0.01
Uranium	0.092	12.2	0.963	1.73
Vanadium	0.066	0.96	0.26	0.11
RADIONUCLIDES				
Radium-226	229.7	786	246.7	303

4.3.5 Restoration Stability Monitoring to Ensure Effectiveness:

A minimum six month groundwater stability monitoring period will be implemented to show that the restoration goal has been adequately maintained. During the stability period, the following restoration stability monitoring program will be utilized:

- Monitoring ring wells will be sampled once every two months and analyzed for the indicator parameters, which include chloride, total alkalinity (or bicarbonate), and conductivity.
- At the beginning, middle, and end of the stability period, the production wells will be sampled and analyzed for the indicator parameters listed in Table 4.2-1 (Baseline Water Quality Parameters).

The NRC and DENR will be contacted if any of the wells cannot be monitored within 65 days of the last sampling event due to unforeseen conditions such as snowstorms, flooding, and equipment malfunctions.

4.3.6 Restoration Schedule

The proposed project restoration schedule, Figure 4.3-1, shows the estimated schedule for restoration. This is a preliminary schedule based on current knowledge of the area, and is based on completion of the production activities for both the Dewey and Burdock sites. As the project is developed, the restoration schedule will be further refined.

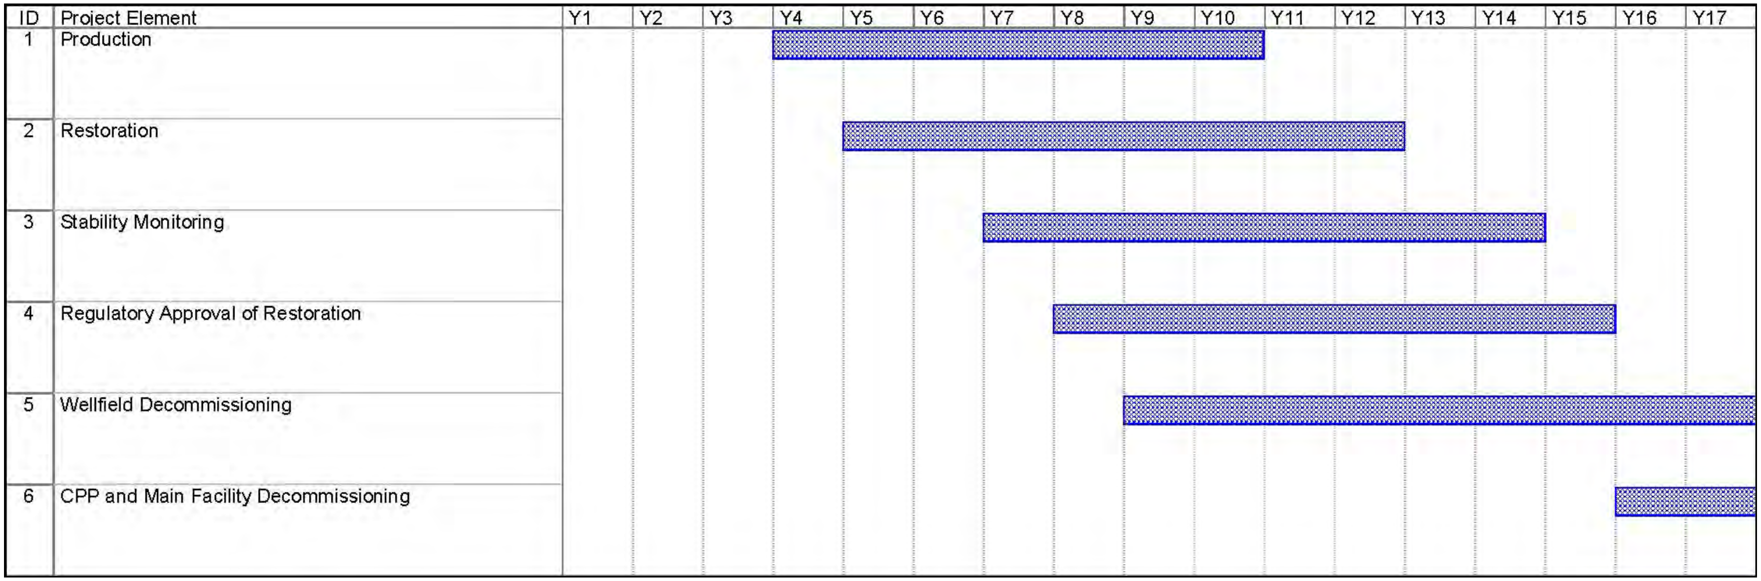

Figure 4.3-1 Proposed Project Operations and Restoration Schedule

4.3.7 Plugging and Abandonment of Wells

Prior to plugging, each well will undergo mechanical integrity testing (MIT) to demonstrate the integrity of casing and cement that will be left in the ground after closure. Alternatively, cementing records or other evidence will be used to show that an adequate quantity of cement is present to prevent upward fluid movement within the borehole outside of the casing. If it cannot be verified that a well casing is grouted properly, an effort will be made to plug the annulus from the bottom of the annulus to the ground surface, using the same materials required for plugging the inside of the casing as described below.

Wells will be opened and debris and downhole equipment such as the tubing, pumps and screens will be removed to prevent obstacles from interfering with plugging operations. The wellhead and casing will be removed to 3 feet below ground surface. A tremie pipe will be used to add grout to wells that are more than 40 feet deep.

Injection, extraction and monitoring wells that are completed into a confined aquifer or multiple aquifers will be plugged with bentonite grout provided the weight of the bentonite grout column will be sufficient to overcome the bottom hole pressure. If bentonite grout will not be sufficient, cement grout will be placed from the bottom of the well to within 8 feet of the ground surface. Cement grout will be placed from 8 feet below ground surface to within 3 feet of the ground surface. The top 3 feet of the well will be backfilled with native material and reclaimed. If a tremie pipe cannot be lowered inside the well-casing for grout placement a tight connection will be made to the top of the casing in order to pump a sufficient volume of cement grout down to fill the well, under pressure. Bentonite grout will not be used if the tight connection method is used.

Figure 4.3-2 shows a generalized schematic of a plugged and abandoned well completed into a confined aquifer or multiple aquifers.

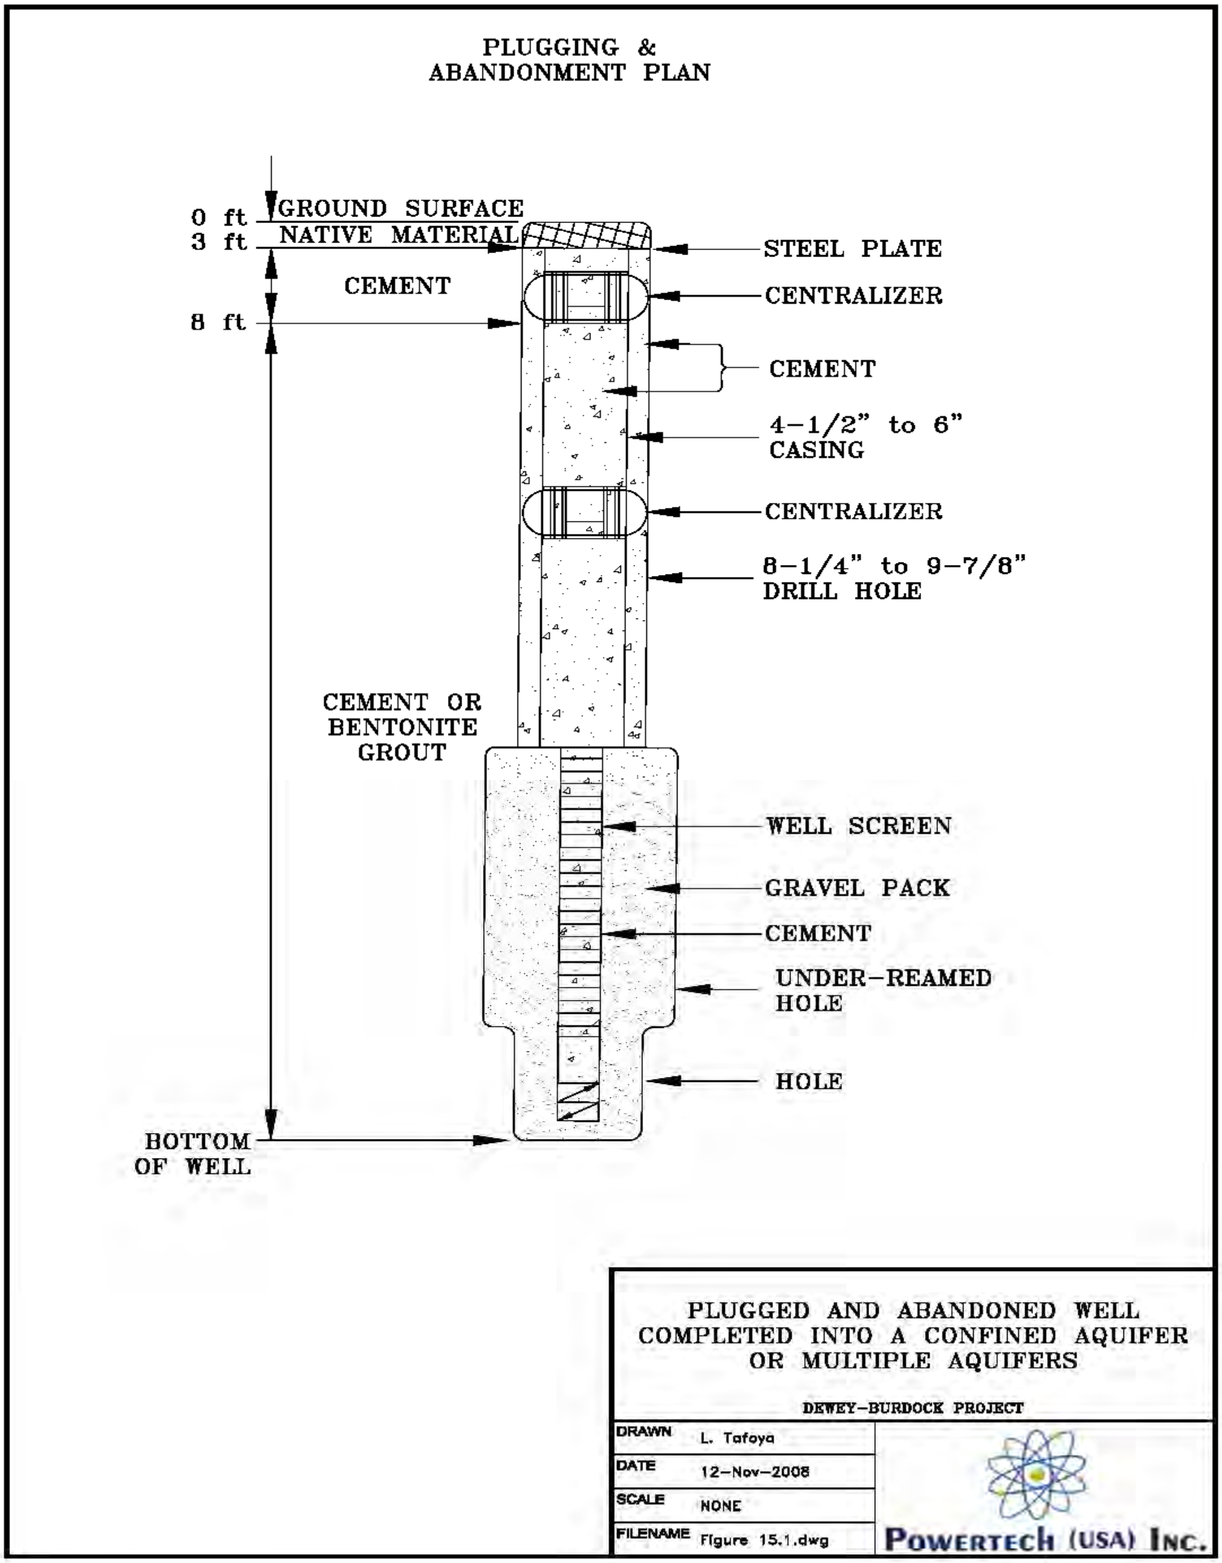

Figure 4.3-2 Plugged and Abandoned Well Completed into a Confined Aquifer or Multiple Aquifers

4.4 Reclamation Cost Estimate

Reclamation cost data is broken down into the following categories according to Estimated Costs in Appendix 4.4-A previously submitted to NRC. See Table 4.4-1 for costs associated with BLM surface disturbance. Costs associated with reclaiming BLM managed lands include total acreage of well fields (9.21 acres) and pipelines and roads (5.04 acres) for a total of 14.2 acres of disturbance. .

Total estimate categories include, but are not limited to;

1. Access Road
2. Plugging and Abandonment of wells
3. Trenches and Pits
4. Solution ponds, settling ponds and other non-tailings impoundments
5. Foundations, facilities and other equipment
6. Revegetation
7. Maintenance and Monitoring
8. Restoration Treatment Chemicals
9. By-product Disposal during Restoration
10. Site Demolition

Table 4.4-1 Estimated Reclamation Cost Associated with BLM Surface Disturbance

Unit cost per well (assume average depth of 650 feet)		
Materials	**Quantity**	**Unit**
5" diameter casing	0.136	Cubic ft/ft
Average well depth	650	ft
Cubic ft per well	88.4	CF
Cement grout cost	9.00	$/cubic ft
Cement grout cost/well	795.60	$/well
Equipment and Labor		
Contractor crew and equipment - at $125/hour		
Mob/DeMob ($11,000 over 377 wells)	30.00	
Well plugging	375.00	$/well
Demolition of well heads and backfill	95.00	
Revegetation	2754	$/15 wells
Equipment and Labor cost/well	500.00	$/well
Total abandonment cost/well	1,300.00	$/well
1st Well field		
Monitoring wells #wells = 15	19,500.00	$
Production and Injection wells #wells = 0	000,000.00	$
Total Estimated Well Abandonment	**22,254**	**$**

Considerations when preparing the cost estimation for reclamation include, but are not limited to:

- Salvageable building and equipment

  - Decontamination, refurbishment, removal of equipment and repairs cost data supplied if applicable:
- Nonsalvageable building and equipment
  - Disposal cost data with tons of material and building volume in cubic meters from each nonsalvageable structure, foundation concrete in cubic feet, process equipment in tons, piping and insulation data provided in lump sum, and electrical and instrumentation cost data provided in lump sum.
- Disposal of chemical solutions within the licensed facility
- Restoration of contaminated area (process area, affected groundwater, surface impoundment residues)
  - According to Criterion 2 of 10 CFR Part 40, Appendix A, 11e.(2) byproduct material must be transported and disposed of at a licensed disposal site. The quantity of removed material, the distance to the disposal site and fees associated with receiving facility will be considered within the final estimated cost of disposal.
- Project Management Costs and Miscellaneous
  - Cost estimations associated with project management, engineering design, review, and change will be submitted within the closure cost estimation along with items such as mobilization; power usage during restoration and reclamation; quality control costs, radiological safety; and any miscellaneous costs not covered under other categories.
- Labor and Equipment Overhead, Contractor Profit
  - Overhead costs for labor and equipment and contractor profit may be calculated one of two ways; as separate items or loaded into hourly rates. If hourly rates are used the unit costs will be identified as a percentage and applied for each area.
- Contingency
  - A minimum of a 15 percent contingency will be applied to the total cost estimate for the final closure of the licensed area.
- Adjustments to Surety Amounts
  - As a requirement outlined in 10 CFR Part 40, Appendix A, Criterion 9, Powertech will adjust the cost estimates annually. This adjustment will account for inflation and changes in reclamation plans; this adjustment will be in the form of a request for amendment to the license.

Changes in reclamation plans include:

- Changes in the process such as size or method of operation
- Licensee initiated changes in reclamation plans or reclamation/decommissioning activities performed
- Adjustments to reclamation plans required by NRC
- Proposed revisions to reclamation plans with cost estimates and the basis for cost estimates detailed for NRC review and approval (see Tables 4.4-2 and 4.4-3 below for cost summaries for land application and disposal well options).

Powertech will provide sufficient information for the NRC to verify that the amount of coverage provided by the financial assurance will permit the completion of all decontamination, decommissioning, and reclamation of licensed area, structures, and equipment used in conjunction with facility operations.

To avoid unnecessary duplication and expense, NRC shall take into consideration surety arrangements required by other federal, state and other local governing bodies per NUREG 1569 Appendix C, 2003.

Table 4.4-2 Cost Summary – Land Application Only

Task No.	Description	Cost
1	Water Treatment Equipment (provided with initial project construction)	-
2	Groundwater Restoration Cost	2,387,000
3	Well Closure	490,000
4	Decommissioning Labor	706,000
5	Mobilization and Site Preparation	25,000
6	Demolition and Disposal of 11e(2)	1,489,000
7	Plant Equipment Transferred	239,000
8	Demolition with Disposal in Landfill	2,520,000
9	Other Reclamation	1,989,000
10	Contingency at 15%	1,477,000
	Total Restoration and Reclamation Cost	11,322,000

Table 4.4-3 Cost Summary – Disposal Well Only

Task No.	Description	Cost
1	Water Treatment Equipment	-
2	Groundwater Restoration Cost	1,877,000
3	Well Closure	490,000
4	Decommissioning Labor	706,000
5	Mobilization and Site Preparation	25,000
6	Demolition and Disposal of 11e(2)	702,000
7	Plant Equipment Transferred	239,000
8	Demolition with Disposal in Landfill	1,228,000
9	Other Reclamation	915,000
10	Contingency at 15%	927,000
	Total Restoration and Reclamation Cost	7,109,000

4.5 Land Use Plans

The information in this section provides data relevant to describe the major land uses within and near the Proposed Action Area (PAA) (Exhibit 4.5-1).

The PAA straddles the western county border between Custer and Fall River, South Dakota. Land within the PAA is predominantly privately owned (97.5 percent) and the remaining 2.5 percent is managed by the Bureau of Land Management (BLM). Exhibit 1.2-1 depicts surface and mineral control in the vicinity of the PAA.

Land use within the proposed project boundary primarily consists of agriculture related to grazing, as well as hunting and historical mining. A 2.0-kilometer review area is not available for the PAA because the four counties in the study area do not utilize zoning or land use plans outside of urban areas. There is no commercial crop production within the permit area, although approximately 388.79 acres of land are irrigated in Sec. 32, T 6S, R. 1E along Beaver Creek. The majority of agricultural production is related to grazing. Most land serves as grazing land for cattle that are sold as food, as well as a small number of horses.

According to the United States Department of Agriculture's (USDA) 2002 census, Custer County generated $11,536,000 and Fall River County generated $49,003,000 from the sale of livestock, poultry and their products. The results from the 2007 Census will not be available until February 4, 2009. According to the National Agriculture Statistics Service, in 2008 (USDA, 2008) the two counties had a combined total 78,000 head of cattle (No data was available for poultry, pig, or sheep inventories). Table 4.5-1 shows the 2008 livestock inventory for Custer and Fall River Counties.

Table 4.5-1 2008 Livestock Inventory for Custer and Fall River Counties

Type of Livestock	Number Custer County	Number Fall River County	Percent of Total (Custer and Fall River combined)
Beef Cows	17,000	45,000	22/58%
All Cattle and Calves – excluding Beef Cows	1,000	15,000	1/19%
Sheep and Lamb	N/A	N/A	N/A
Hogs and Pigs	N/A	N/A	N/A
Total Animals	18,000	60,000	100%

Source: USDA 2008.

Recreation lands are present in Custer, Fall River and Pennington counties within a 50-mile radius of the PAA (Table 4.5-2). Major attractions include Mount Rushmore National Memorial and Wind Cave National Park which are set in the backdrop of the Black Hill National Forest. Within the PAA or within the surrounding 2.0 kilometers there are no recreation lands present because most of the land is private with a small portion (240 acres) belonging to the BLM.

Recreational use within the PAA is limited primarily to large game hunting. Within the PAA, hunting is currently open to the public on approximately 5,689 acres. Approximately 240 acres are owned by the BLM; the South Dakota Game Fish and Parks (SDGFP) lease around 3,069 acres annually of privately owned land and currently designate this acreage as walk-in hunting areas.

Table 4.5-2 Recreational Areas within 50 Miles of the PAA

Name of Recreational Facility	Managing Agency	Distance From PAA (miles)
Mount Rushmore National Memorial	U.S. Department of the Interior	44.0
Jewel Cave National Monument	U.S. Department of the Interior	23.0
Buffalo Gap National Grassland	U.S. Forest Service	3.0
Custer State Park	South Dakota Department of Game, Fish and Parks	35.0
Wind Cave National Park	U.S. Department of the Interior	29.0
Black Hills National Forest	U.S. Forest Service	0.25
Angostura State Recreation Area	South Dakota Department of Game, Fish and Parks	29.0
George S. Mickelson Trail	South Dakota Department of Game, Fish and Parks	17.0

Source: Google Earth (20 June, 2008)

Table 4.5-3 lists the distance to the nearest resident from the PAA according to 22.5-degree sectors centered on the 16 cardinal compass points. The nearest resident is 0.9 miles to the west south-west of the PAA.

Table 4.5-3 Distance to Nearest Resident from the Center of the Proposed Project

Sector	Distance from Project Center	
	Miles	Km
N	7.2	11.6
NNE	8.3	13.3
NE	6.7	10.8
ENE	13.1	21.1
E	6.8	11.0
ESE	10.7	17.3
SE	7.5	12.1
SSE	5.9	9.4
S	0.9	1.4
SSW	3.4	5.5
SW	21.0	33.7
WSW	1.7	2.7
W	20.3	32.6
WNW	6.2	10.0
NW	3.5	5.6
NNW	4.2	6.7

Data from US Census Bureau, 2000 Census

Aesthetics

The PAA is located within the Great Plains physiographic province on the edge of the Black Hills Uplift. The vegetation is a mix of short grasses and shrubs typical of semi-arid steppe land along with Ponderosa Pine forest toward the Black Hills. The color of the landscape varies from light brown and green to dark green with wildflowers in the springtime to light brown to golden during the later drier months. The human influence on the area is minor with most of the area being used for grazing activities and associated facilities (e.g., fences and stock wells). The area's infrastructure includes the Burlington Northern Rail Road (BNRR) that runs north through Edgemont towards Newcastle, Country Road 6463 that parallels the BNRR to the town of Dewey and overhead electricity lines and several gravel access roads.

Transportation and Utilities

The PAA generally will be accessed north from Edgemont along County Road 9. To the east U.S. Highway 18 connects Edgemont with Hot Springs and to the north State Highway 89 connects Edgemont with Custer City. Annual Average Daily Traffic (AADT) counts on U.S. Highway 18 between Edgemont and the junction with State Highway 89 is 2,000 vehicles (South Dakota Department of Transportation [SDDOT] 2007). The AADT count on State Highway 89 between Custer City and the junction with U.S Highway 18 is 515 vehicles (SDDOT 2007).

Fuel Cycle Facilities

The NRC provides a list of all of the source material facilities operating in the United States which include uranium mills and fuel cycle facilities. According to the NRC website there are no fuel cycle facilities within 50 miles of the PAA. The closest fuel cycle facility is the AREVA NP, Inc. uranium fuel fabrication in Richland, Washington. Also in Eunice, New Mexico the Louisiana Energy Services fuel cycle facility is currently under construction (NRC, 2008).

There are no Resource Material Licenses for in situ uranium projects within 50 miles of the PAA. The nearest operational in situ facility is the Crow Butte ISL facility, SUA-1534, in Darrow County, near Crawford, Nebraska (NRC, 2008).

POWERTECH (USA) INC.

Section 5.0 - Environmental Protection and Monitoring Plan

The Environmental Protection and Monitoring Plan is designed and submitted in an effort to demonstrate the measures that will be taken to prevent unnecessary or undue degradation during operations (§3809.301.(b)(2)(i) and 3809.311.(c)). Presented within this plan are the baseline environmental data that was collected within the proposed permit boundary and outside the permit boundary within a two kilometer radius. An evaluation was conducted to determine potential impacts for each action taken during each phase of the proposed mining operation; environmental controls and mitigation initiatives are also discussed in this plan.

5.1 Radiological

For radiological characterization of the PAA three primary guides were utilized, NUREG-1569 "Standard Review Plan (SRP) for In Situ Leach Uranium Extraction License Applications" (NRC 2003), "NRC Regulatory Guide (RG) 4.14" (Revision 1), "Radiological Effluent and Environmental Monitoring at Uranium Mills" (NRC 1980) to provide an acceptable basis for pre-operational radiological baseline evaluations, NUREG-1575, Multi-Agency Radiation Survey and Site Investigation Manual (MARSSIM), 2000 was also considered where relevant.

Sample placement prescribed by RG 4.14 was modified in order to ensure the effort put forth in characterization of the PAA is adequate and assures an appropriate baseline determination of background radiation. Modification of the sampling program described in RG 4.14 is appropriate as RG 4.14 was developed to be used in design of an environmental monitoring program for conventional uranium mill and tailings sites and was not specifically intended to address ISL operations. The modified sampling program adequately characterized radiological aspects of the environment at the PAA and assists the applicant in the proper placement of operational monitoring sites to ensure standards for protection against radiation will be met during licensed operations. The sampling protocol was designed to achieve the goal of adequately protecting the public and the environment from unacceptable levels of radiation or radioactive materials that exceed background levels. See Section 5.1.3 for additional details.

Responsible operators achieve this goal, in part, by consulting NRC guidance documents such as NUREG-1575. By conducting a detailed environmental site survey, sampling and analysis program; the operator is able to establish baseline background levels and assess possible derived concentration guideline levels (DCGLs) via both historical site assessments (HSA) and the most recent site characterization. Historical and current data will be assessed prior to commencement of the Proposed Action's D&D (Decontamination and Decommissioning) program. By utilizing the immense experience of the industry, consultation with the appropriate regulators and utilization of applicable guidance, the licensee will be able to clean up any contamination that may result from ISL operations and release the site for unrestricted use.

5.1.1 Baseline Radiological Data

This section provides baseline radiological data for surface soils (0-5 and 0-15 cm), subsurface soils to a depth of 1 m, vegetation, cattle, direct gamma radiation, and radon-222 flux rates radon-222 in air representative of the project property. The work was performed by Environmental Restoration Group (ERG) between August 2007 and July 2008.

Field investigations, sample collection, and other quality-related work performed were conducted in accordance with applicable ERG Standard Operation Procedures (SOPs), listed below:

- SOP .010 Radon Flux Canister Deployment
- SOP 1.05 Calibration of Scaler, Rate meters

- SOP 1.22 Determining the Concentration of Airborne Radioactive Particles
- SOP 1.51 Correlation between Gamma-Ray Count Rate and Exposure Rate
- SOP 2.02 General Equipment Decontamination
- SOP 2.07 Function Check of Equipment
- SOP 2.09 Correlation between Gamma-Ray Measurements and Radium-226 in Soil
- SOP 3.02 Sample Control and Documentation

- SOP 7.09 Vegetation Sampling

The baseline radiological field investigation consisted of the following activities:

- A GPS-based gamma survey conducted at 100 to 500 meter (m) transects spanning the PAA
- A second GPS-based gamma survey of two, collective land application areas conducted at 100 m transects
- Collecting surface soil (0-15 centimeter [cm]) samples at 75 randomly selected and at five biased locations spanning the PAA
- Collecting subsurface soil samples at nine randomly selected locations taken at depth intervals of 15-30 cm and 30-100 cm
- Collecting surface (0-15 cm) and subsurface samples at the same depth intervals at 17 randomly selected locations in the land application areas
- Collecting shallow (0-5 cm) surface soil samples at the eight AMS
- Vegetation sampling at each AMS during the summer, fall and spring
- Air monitoring at one background and seven additional locations
- Radon monitoring in air
- Radon flux measurements at locations coinciding with the subsurface samples
- Exposure rate monitoring, using a PIC and thermoluminescent detectors (TLDs)
- Collecting three samples of locally grazed livestock

Table 5.1-1 summarizes the scope of the field investigation and Exhibit 7.9-1 shows the sampling location and type of sampling performed in the PAA. All samples were shipped under chain-of-custody to a National Environmental Accreditation Conference-certified laboratory, Energy Laboratories, in Rapid City, South Dakota.

The units reported in the body, tables, and figures related to this section vary. NRC RG 4.14, *Radiological Effluent and Environmental Monitoring at Uranium Mills*, has specific requirements for unit reporting in tables. For example, it recommends that radionuclide soil concentrations be reported in units of microcuries per gram (µCi/g). Where applicable, the tables adopt this unit. The main body of Section 5.1, however, adopts the unit pCi/g for this parameter, as this unit is used more generally and consistently by the uranium industry and public.

Table 5.1-1 Summary of Baseline Radiological Investigation Scope

Task Method/Endpoint	Baseline Investigation Scope	Parameters Evaluated
A.GPS-Based Gamma Surveys	GPS-based unshielded gamma-ray readings along 100 or 500 meter transects at $\leq$1.5 meters per second. A second survey covered land application areas along 100 meter transects.	Serve as basis to estimate pre-operational gamma emissions from land areas and exposure rates, surface soil radium-226 concentrations, and identify areas for biased soil sampling.
B. Biased Soil Sampling	Biased samples at five locations, all collected from 0 to 15 cm	Radium-226 for all samples Thorium-230, natural uranium, lead-210 for 2 locations
C. Random Soil Sampling	Random samples at 75 locations Nine of the 75 locations were sampled at depth (15-30 cm and 30-100 cm) Ten duplicates at 0 to 15 cm. One duplicate each at 15 to 30 cm and 30 to 100 cm.	Radium-226 for all samples Thorium-230, natural uranium, lead-210 (8 from 0 to 15 cm and one each at 15 to 30 cm and 30 to 100 cm
D. Soil sampling in land application areas	Random samples at 17 locations, all but one of which were sampled at 0 to 15, 15 to 30 and 30 to 100 cm. Refusal was encountered at 45 cm in the exceptional location. One duplicate each at 0 to 5, 15 to 30, and 30 to 100 cm.	Radium-226, thorium-230, natural uranium, and lead-210 for all samples
E. Exposure Rate Monitoring	Exposure rate determinations based on TLD and PIC measurements. TLD measurements collected for four quarters.	Exposure rates
F. Soil and Vegetation Sampling at Air Monitoring Stations	Eight locations: seven on-site (AMS-01 through AMS-07) and one located approximately 1.9 miles west of the southwest corner of the PAA (AMS-BKG). Vegetation samples collected for four quarters.	Vegetation: radium-226, thorium-230, natural uranium, lead-210 and polonium-210 Soil: All of the above except polonium-210
G. Air Particulate Sampling	Eight locations: seven on-site (AMS-01 through AMS-07) and one located approximately 1.9 miles west of the southwest corner of the PAA (AMS-BKG). Air particulate samples collected for four quarters.	Air filters: radium-226, thorium-230, natural uranium, lead-210 and polonium-210
H. Radon in air	16 locations: eight AMS and eight additional locations. Radon in air measurements taken for four quarters.	Radon-222
I. Radon Flux Measurements	Radon flux measurements at nine locations (collected at the biased subsurface soil sample locations in Task C) in summer, fall, and spring.	Radon-222
I. Locally Grazed Livestock Sampling	Three samples collected from one locally grazing cow.	Radium-226, thorium-230, natural uranium, lead-210 and polonium-210

5.1.2 Gamma Survey

5.1.2.1 Baseline GPS-Based Gamma Survey

GPS-based gamma surveys were conducted within the PAA and the historical surface mine areas of the project from September 13-27, 2007 and completed on July 14, 2008. Unshielded Ludlum Model 44-10 2”x 2” sodium iodide (NaI) detectors were coupled to Ludlum Model 2221 ratemeter/scalers (set in ratemeter mode) and a Trimble Pro XRS GPS Receiver with Trimble TSCe Datalogger. Survey transects were spaced at approximately 500-m intervals in the PAA and 100 m in the surface mine area. The transect spacing was reduced in the surface mine area in anticipation of finding a greater variation in gamma-ray emissions, due to historical mining in the area. The survey speed was maintained between 2 and 5 feet per second with x- and y-coordinates and gamma-ray count rates recorded every second. The detector height was held relatively constant at approximately 18 inches above ground surface. Depending on the terrain, field personnel surveyed using ATVs or by walking with the equipment in backpacks. See example of utilization of best technology available in regards to conducting the roving gamma survey at the PAA in Figure 5.1-1.

A second GPS-based gamma survey was conducted over the land application areas from July 17-19, 2008, using the Ludlum gamma-ray detection system described above with the same response characteristics as used in the initial survey. The scanning speed and detection height were unchanged from the initial survey and the transect spacing was 100 m.

The areas subject to GPS-based gamma surveys are shown on Figure 5.1-2.

Figure 5.1-1 Example of Best Technology Available Utilized for the Roving Gamma Survey at the Dewey-Burdock Project by ERG

POWERTECH (USA) INC.

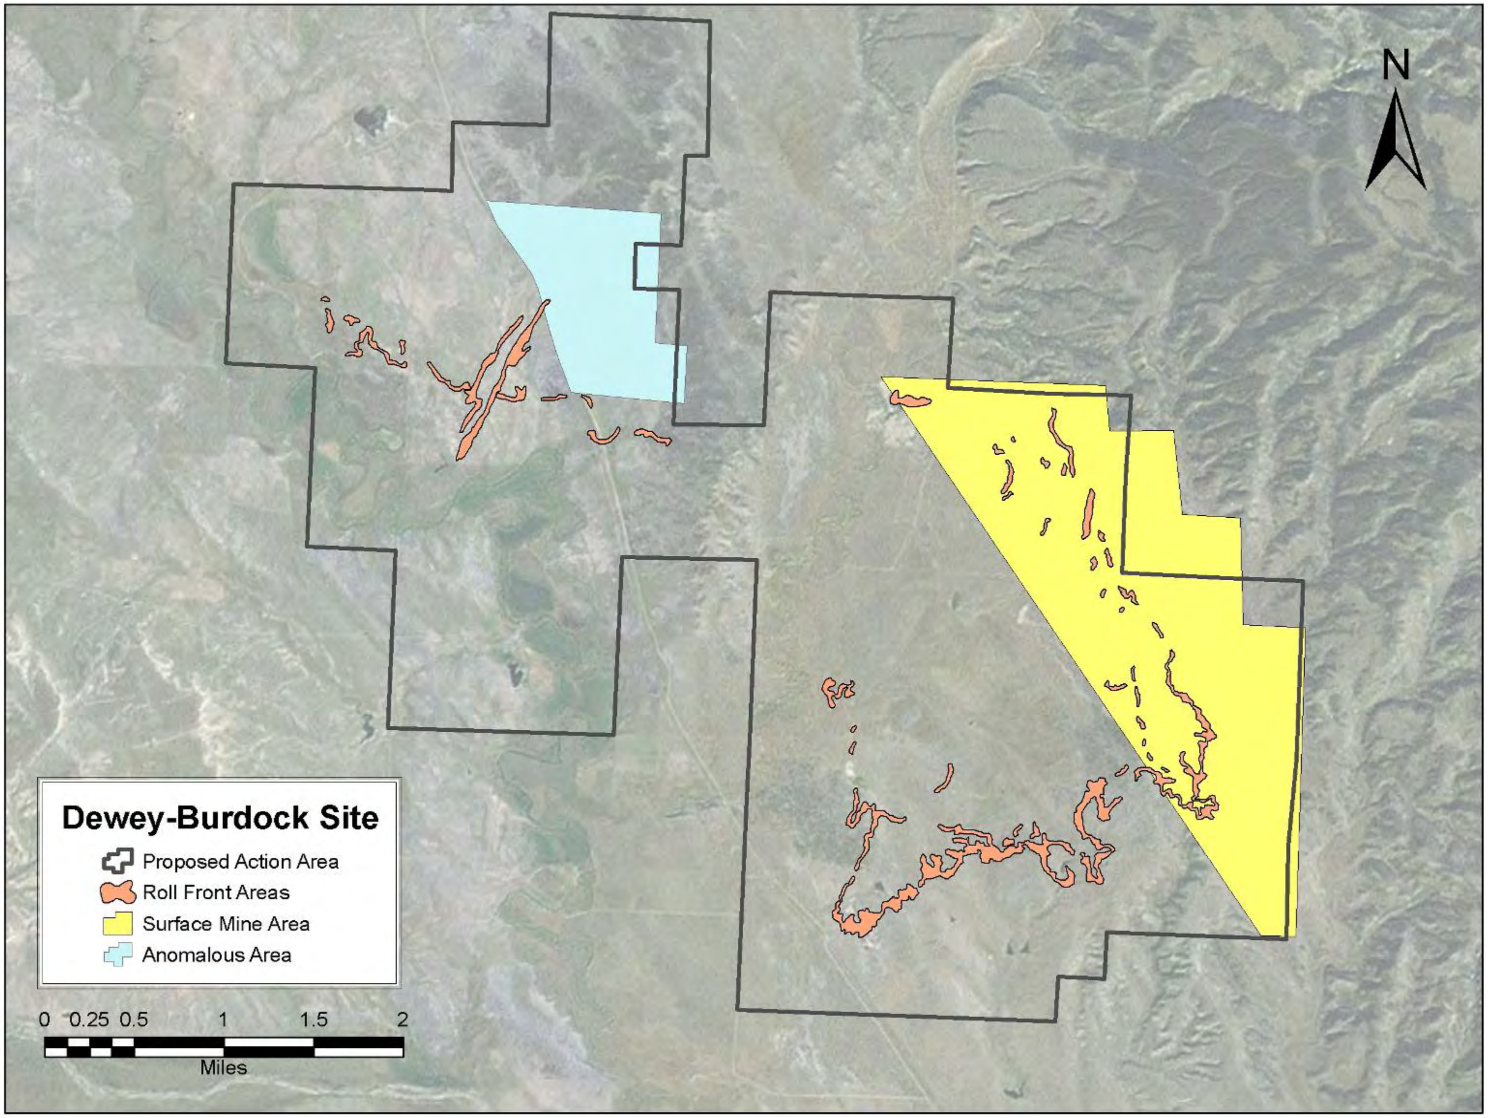

Figure 5.1-2 Areas Subject to GPS-Based Gamma Surveys

5.1.2.1.1 Cross-Calibration of Sodium Iodide Detectors and a High-Pressure Ionization Chamber

Both the sodium iodide detector and PIC measure gamma radiation. The sodium iodide detection system measures the rate that the gamma rays interact with the detector in counts per minute (cpm), has a lower sensitivity than the PIC and is energy dependent. The PIC is a highly accurate ionization chamber for measuring exposure rate in microroentgens per hour (μR/hr) but requires a longer count time. The PIC was used because it measures exposure rates directly and is considered a primary standard by NIST, when calibrated. The PIC measures gamma, X-rays, and cosmic radiation without discrimination. It is highly stable, relatively energy independent, and serves as an excellent tool to calibrate other survey equipment to measure exposure rates. Because of its portability and shorter measurement times, the sodium iodide detector is more efficient than the PIC for use in large area surveys. By performing the large area gamma surveys with sodium iodide detectors, then developing a correlation between the two instruments, exposure rates derived from the sodium iodide measurements can represent site wide gamma emissions from surface soils.

Powertech collected 12 co-located static gamma counts and exposure rate measurements to develop the correlation between gamma counts and exposure rates. The locations were biased towards areas where gamma shine was not relatively high; that is, where gamma count rates remained relatively constant at 18 inches, 1 m, and 2 m above ground surface. In addition, locations were chosen to encompass most of the range of sodium iodide detector readings observed in the GPS-based gamma surveys. The sodium iodide measurements were taken using one of the 2-inch by 2-inch sodium iodide detectors that were used in the baseline gamma survey. A 1-minute integrated count was taken at each of the 12 locations with the detector suspended at 18 inches above the ground surface. Exposure rate measurements were then collected at a 1-m height at each location, directly above the location where the sodium iodide detector was held. Exposure rates were determined after 20-minute integrated counts. The PIC and gross gamma measurements were performed on July 14 to 16, 2008 at the locations shown on Figure 5.1-3.

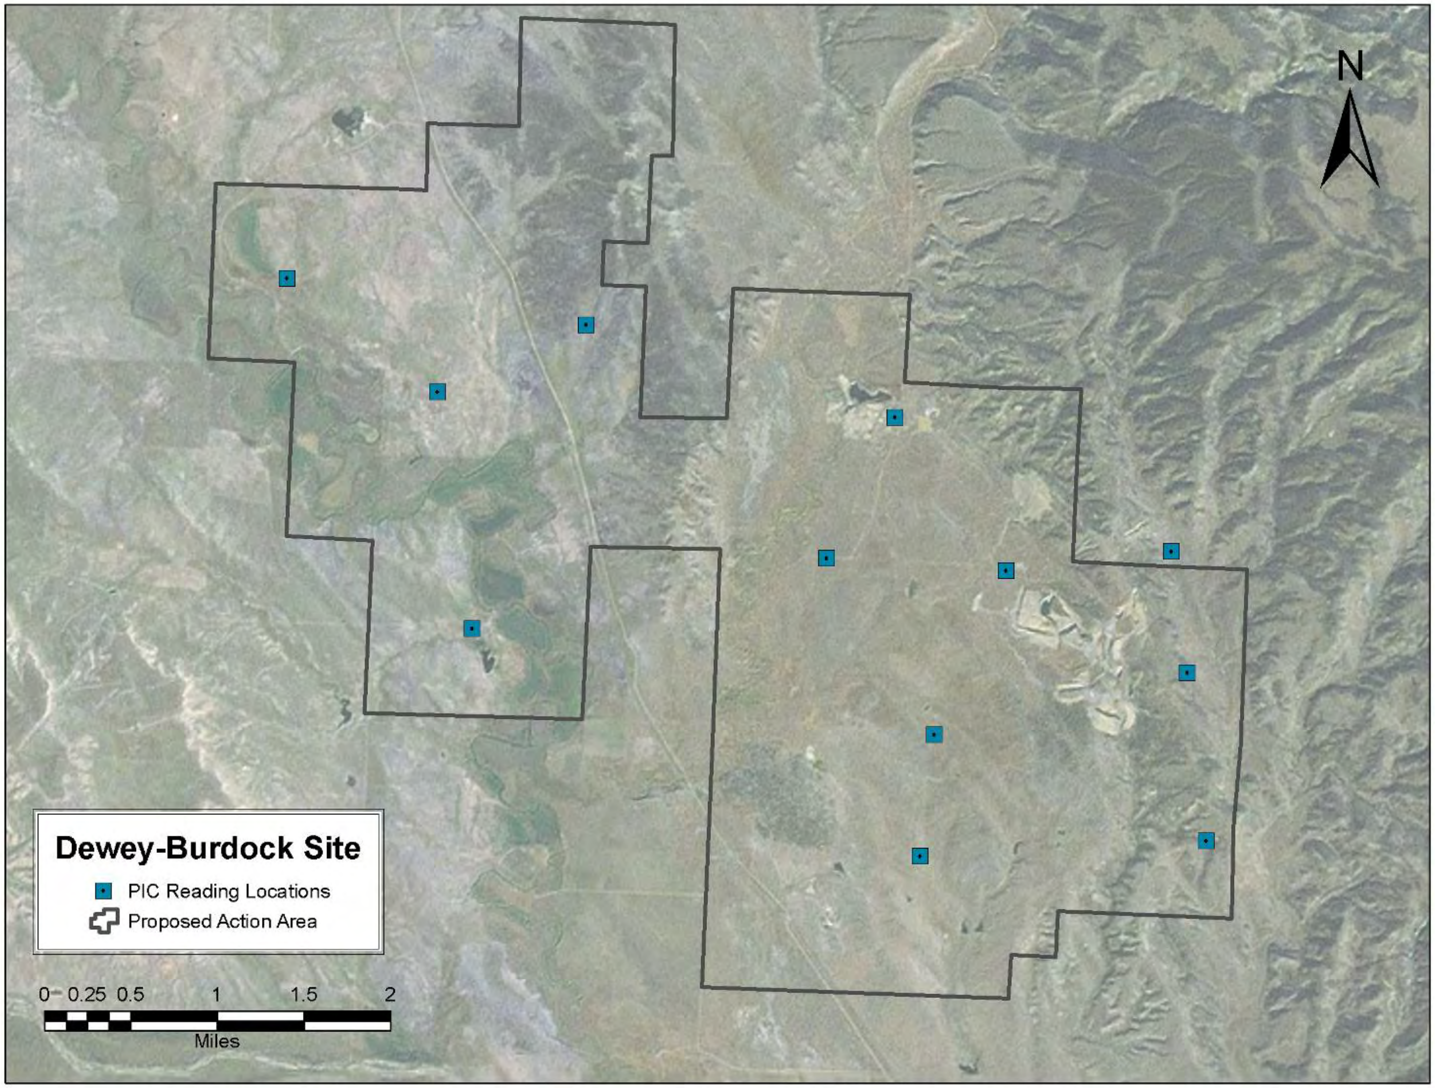

Figure 5.1-3 Locations of High Pressure Ion Chamber and Sodium Iodide Detector Measurements

5.1.2.1.2 Gamma/Radium-226 Correlation Grids

To estimate site-wide radium-226 concentrations at each of the GPS-based gamma survey points, a correlation was established by performing a regression between the surface soil analytical results for radium-226 in the 80 surface (0-15 cm) soil samples and one-minute integrated direct radiation measurements collected at each of these locations prior to sample collection. The measurements were collected with the same Ludlum 44-10/2221 2-in by 2-in sodium iodide gamma detection systems used in the GPS-based gamma survey.

The correlation was used to translate each of the gamma-ray count rates obtained in the GPS-based survey to predicted radium-226 concentrations. Arc GIS then was used to generate average predicted radium-226 concentrations in 700 by 700 foot grid blocks covering the site.

5.1.2.1.3 Data Quality Assurance/Quality Control

All survey instruments were calibrated. The function of survey instruments was checked at the beginning and end of each work day using a National Institute of Standards and Technology-traceable cesium-137 source. Calibration sheets and function check data have been retained.

5.1.2.2 Gamma Survey Results

The gamma-ray count rate data obtained in the initial survey were first evaluated as an entire set and then subdivided into the main permit (the entire data set less the surface mine area) and surface mine areas.

The observed gamma-ray count rates are presented as colors representing ranges of counts in Figure 5.1-4. Three areas are shown on the figure: the main permit and surface mine areas, and an area of anomalous gamma-ray count rates located in the northern portion of the PAA.

POWERTECH (USA) INC.

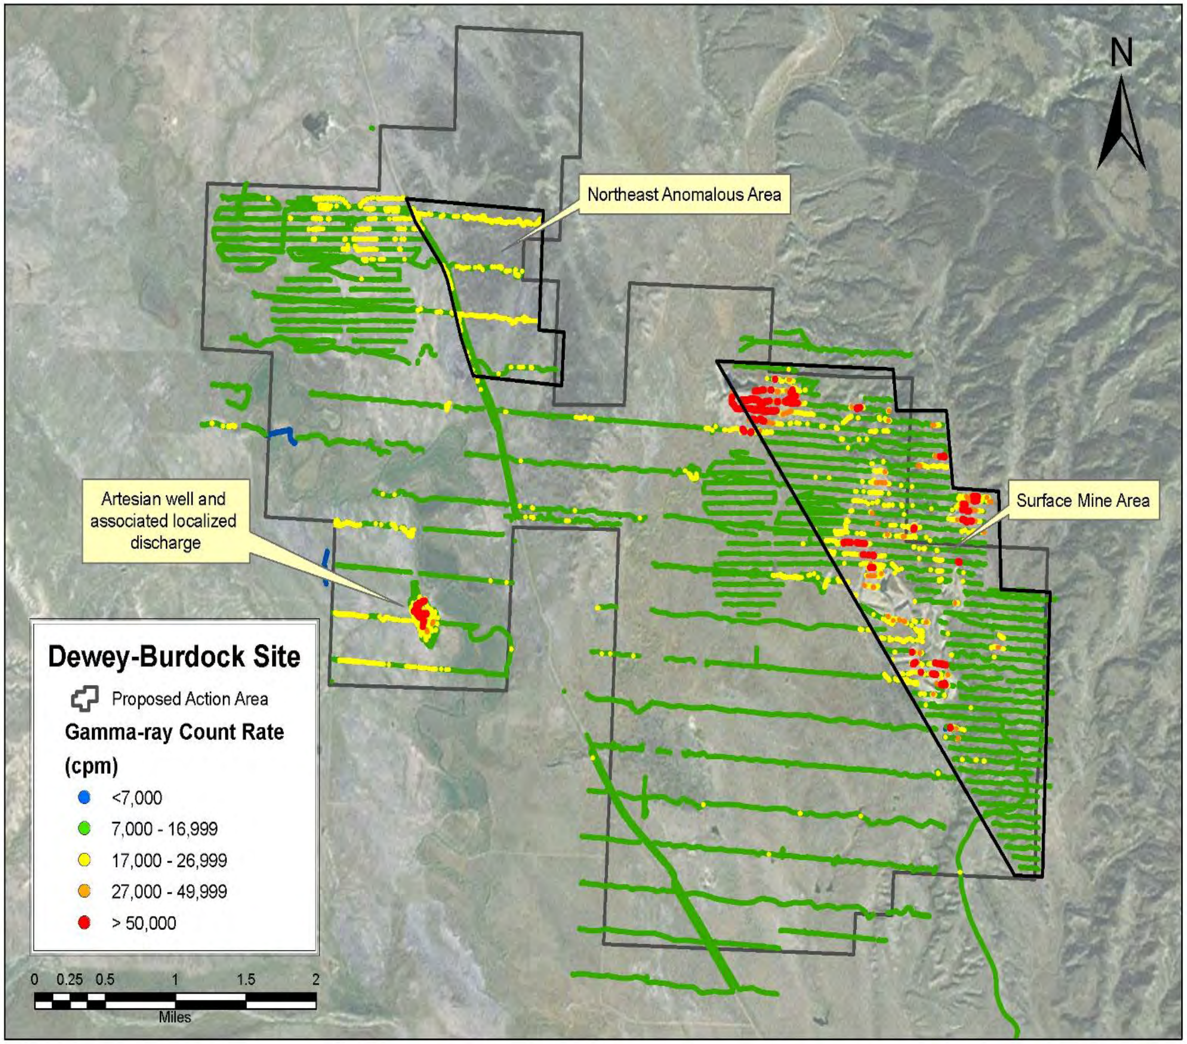

Figure 5.1-4 Gamma-Ray Count Rates Obtained During Initial GPS-Based Gamma Survey

None of the data sets: including the entire PAA and gamma data obtained in the main permit and surface mine areas are normal, lognormal, or exponentially distributed. Furthermore, normalizing data transformations were conducted and the transformed data did not follow standard distributions. For these reasons, data analysis and summaries were performed using non-parametric statistical methods, which are less sensitive to extreme observations typical of skewed data distributions.

The median and inter-quartile ranges (IQR) are non-parametric measures of central tendency and variability, respectively. The IQR is the difference between the first (Q1) and third (Q3) quartiles, i.e., 25 and 75 percent of the data area less than Q1 and Q3, respectively. Any datum that is outside the range of 1.5 times the IQR lower than Q1 and 1.5 times the IQR higher than Q3 is considered an outlier. Extreme outliers, or extremes, are those exceeding three times the IQR to the left and right from the first and third quartiles respectively (Ott and Longnecker, 2001).

The summary statistics of the GPS-based gamma-ray survey are listed in Table 5.1-2. The median of the gamma-ray count rates for the overall data set was 12,687 cpm. Field personnel collected 157,075 readings ranging from 5,550 to 460,485 cpm.

Table 5.1-2 Statistical Summary of Gamma-Ray Count Rates in Entire Data Set, Main Permit and Surface Mine Areas

	Gamma-Ray Count Rate (cpm)		
Estimator/Endpoint	Entire Data Set	Main	Surface Mine Area
Mean	15,025	13,073	16,823
Standard Deviation	17,095	2,995	23,377
Median	12,687	12,664	12,717
Mode	12,487 (n=53)	12,585 (n=35)	12,138 (n=31)
Minimum	5,550	5,883	5,550
Maximum	460,485	171,243	460,485
Q1	11,395	11,598	11,125
Q3	14,437	14,137	14,783
IQR	3,042	2,539	3,658
No. of Counts	157,075	75,345	81,757

Notes:
Entire data set does not include gamma-ray counts obtained along the eastern haul road. In addition, the sum of the counts in the main permit and surface mine areas is 27 counts greater than the counts in the entire data set, due to an overlap in counts within the two shapes placed as a layer in ArcView GIS to select the data sets .

Proposed Action Area

As shown in Table 5.1-3, the median gamma-ray count rate for the PAA data set was 12,664 cpm for 71,148 observations. The count rates ranged from 5,883 to 171,243 cpm. Low outliers in the PAA data set, count rates below 7,790 cpm, appear to be limited to two clusters. High outliers in the data set, count rates exceeding 17,946 cpm, appear to be limited to an approximately 600-acre located at the north end of the PAA, the area identified as an anomalous area on Figure 5.1-4.

Approximately 0.1 and 2 percent of the gamma-ray count rates observed in the PAA are comprised of low and high outliers, respectively.

The majority of high outliers are located in the north section of the PAA. The distribution of these anomalous gamma-ray count rate data is unknown. The count rates ranged from 8,863 to 22,130 cpm and the median was 15,503 cpm.

POWERTECH (USA) INC.

Surface Mine Area
In the surface mine area, the gamma-ray count rates ranged from 5,550 to 460,485 cpm and the median was 12,717 cpm. In general, clusters of higher readings are associated with un-reclaimed open pit uranium mines, waste rock, rocky outcrops, and drainages in the surface mine area. Approximately 0.004 and 9 percent of the gamma-ray count rates observed in the surface mine area are low and high outliers, respectively.

Discussion
There is sufficient evidence for the variances in the main permit and surface mine area gamma-ray count rates being distinct and thus represent distinct data populations. The variances in the main permit anomalous area are also distinct.

It is clear that the surface mine area in the eastern quarter of the site exhibits radiological impacts from historic and/or current anthropogenic activities within the area. In addition, gamma-ray count rates in the anomalous north area also are clearly distinct from those in the wider main PAA. The precise sources of the differences are not relevant in the context of this investigation since they are part of the baseline or background radiological characteristics of the site.

Land Application Areas
The summary statistics of the GPS-based gamma-ray survey of the proposed land application areas are listed in Table 5.1-3. The gamma-ray count rates obtained in the main PAA are listed in the table to facilitate comparison between the proposed land application areas and area in which they occur. The data are shown as ranges of count rates on Figure 5.1-5.

Gamma-ray count rates in the proposed land application areas are similar to those obtained in the larger main PAA. In the Dewey land application area, the median of the gamma-ray count rates was 12,523 cpm. Field personnel collected 23,480 readings ranging from 6,798 to 20,422 cpm. In the smaller, Burdock land application area, the median of the gamma-ray count rates was 12,232 cpm. Field personnel collected 13,647 readings ranging from 8,498 to 24,248 cpm.

Table 5.1-3 Statistical Summary of Gamma-Ray Count Rates in Proposed Land Application Areas

	Gamma-Ray Count Rate (cpm)

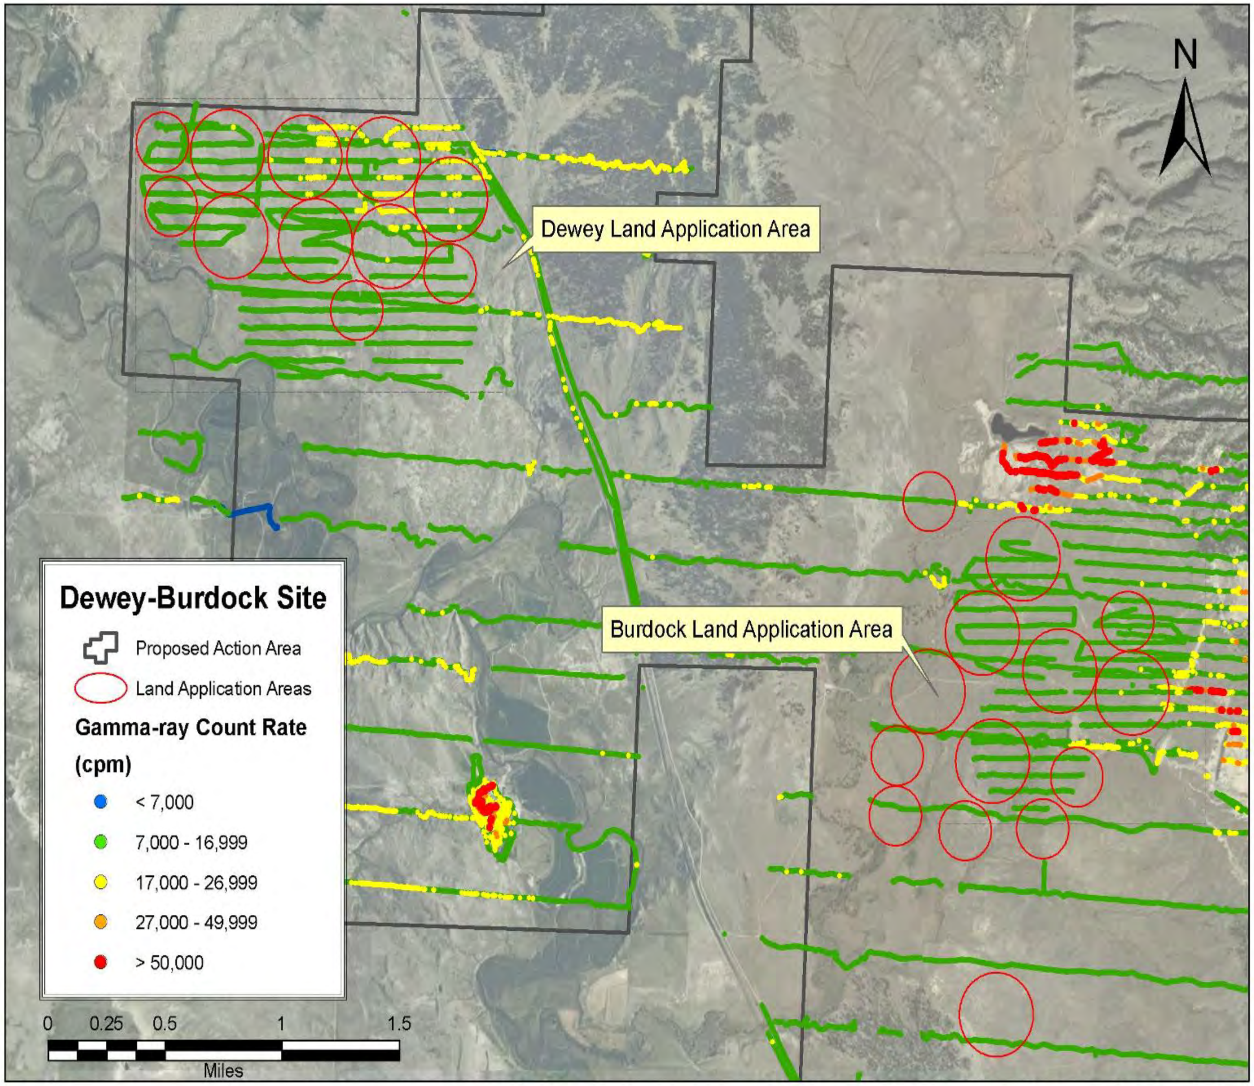

Figure 5.1-5 GPS-Based Gamma-Ray Count Rates in the Land Application Areas

5.1.2.2.1 Cross-Calibration of Sodium Iodine Detectors and a High-Pressure Ionization Chamber

The linear equation representing the correlation between exposure rates and gamma-ray count rates, determined using the PIC and average of the two sodium iodide detectors is:

$$Exposure\ Rate = 0.0007\ x\ Gamma\ Count\ Rate + 2.02$$

where the exposure rate is in gross µR/hr and the gamma count rate is in gross cpm.

The linear regression model for the average is a good fit, with an R2 of 0.96. Nearly all of the data align along the slope of the line, as shown in Figure 5.1-6. The correlations are similar for the individual sodium iodide detectors and not discussed further.

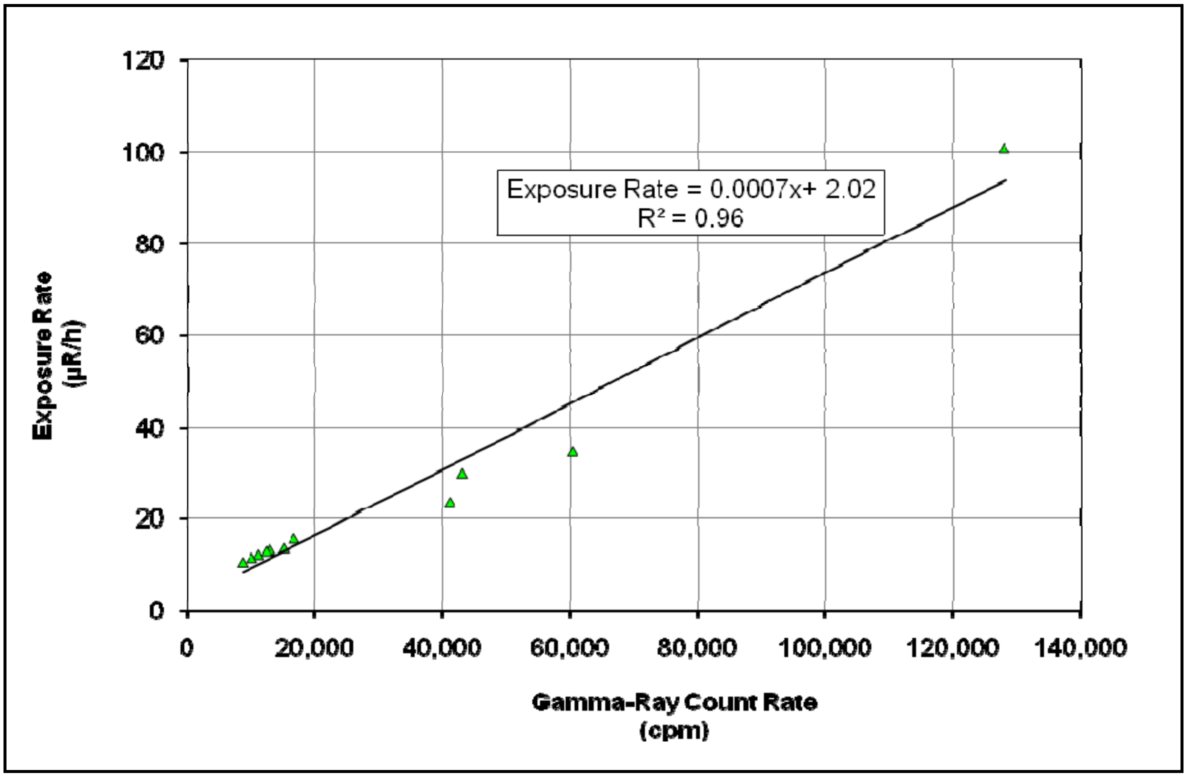

Figure 5.1-6 Linear Regression Model: Exposure Rates Correlated to Gamma-Ray Count Rates

The linear regression model predicts an average exposure rate of 10.9 µR/hr for the site. The range of predicted exposure rates is 5.9 to 324 µR/hr, based on the observed gamma-ray count rates at the site. The predicted site-wide exposure rates are shown as ranges of colors in 700 by 700 foot grid block averages on Figure 5.1-7.

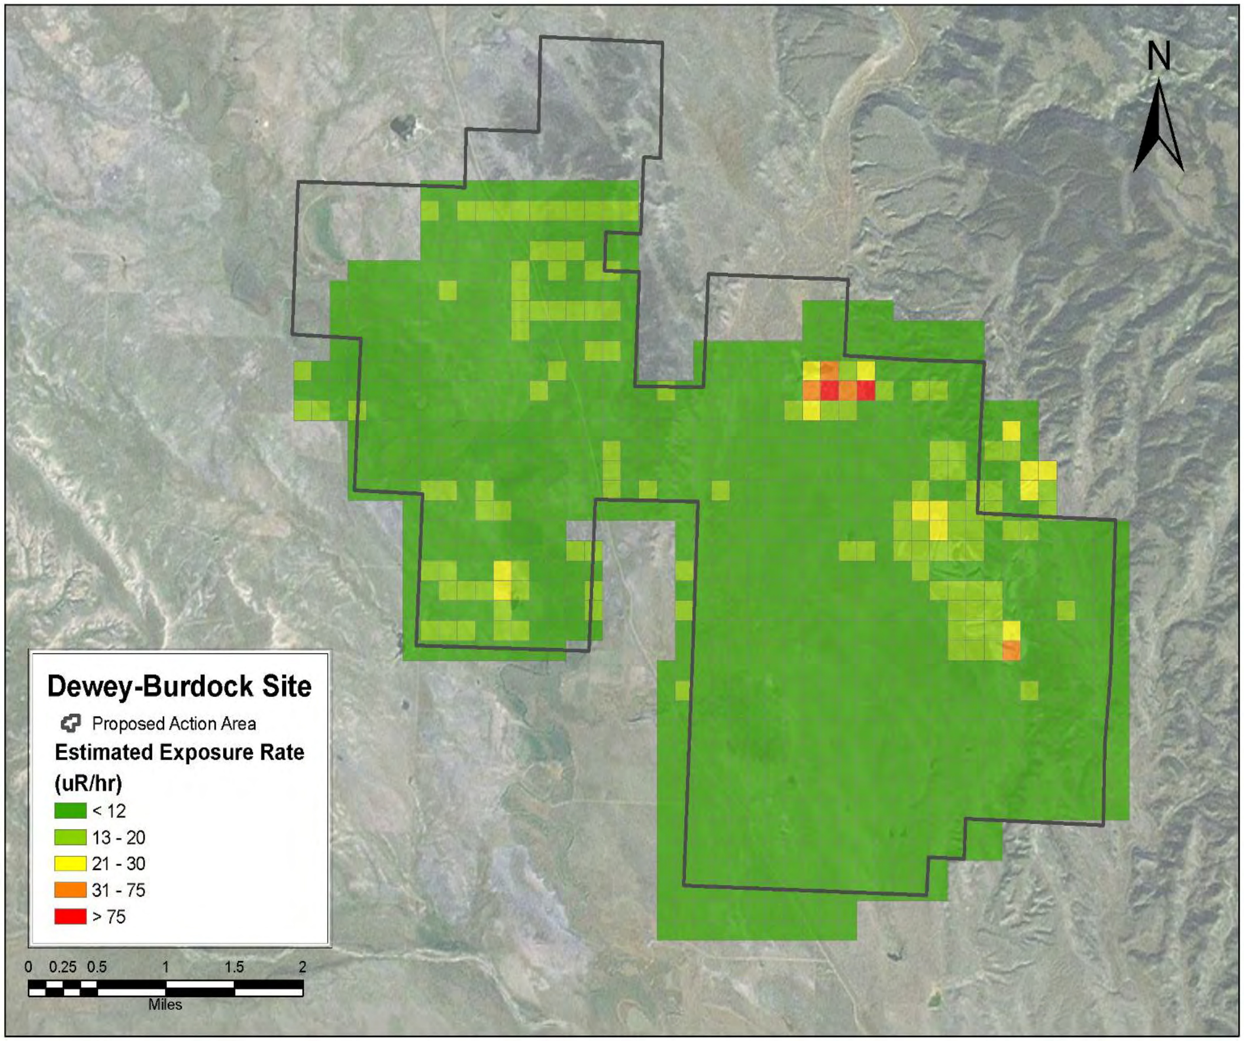

Figure 5.1-7 Predicted Site-Wide Exposure Rates, Grid Block Averages

5.1.2.2.2 Gamma-Ray Count Rate-Soil Ra-226 Concentration Correlation Grid Results

The relationship between gamma-ray count rates and radium-226 concentrations was determined to be appropriate after five outliers were removed from the set of 80 data points. The equation of the linear fit is:

$$Radium\text{-}226 = 1.9*10^{-4} \times Gamma\text{-}Ray\ Count\ Rate\ -1.04$$

where the radium-226 concentration is in pCi/g and the gamma-ray count rate is in gross cpm.

This model has an R2 of 0.43, with 0.43 accounting for 43 percent of the variance in the data set. Table 5.1-4 lists summary data for the predicted radium-226 concentrations in each of the major areas.

Of the 1,015 grid blocks covering the entire PAA, the majority (approximately 78 percent) of the interpolated surface radium-226 concentrations is less than 1.5 pCi/g. In the overall data set, the median predicted radium-226 concentration is 1.1 pCi/g and the range is 0.0 to 24.9 pCi/g. In the main PAA (excluding the anomalous area), the median predicted radium-226 concentration is 0.0 pCi/g and the range is 0.0 to 9.0 pCi/g. In the surface mine area, the median predicted radium-226 concentration is 1.5 pCi/g and the range is 0.0 to 24.9 pCi/g. In the anomalous portion of the main PAA, the median predicted radium-226 concentration is 1.4 pCi/g and the range is 0 to 2.3 pCi/g.

Table 5.1-4 Summary of Predicted Radium-226 Concentrations in Grid Blocks

		Predicted Radium-226 Concentration Based on Average of Counts Within Grid Block (pCi/g)					
Data Set	**No. of Grid Blocks**	**Median**	**Minimum**	**Maximum**	**Q1**	**Q3**	**IQR**
All Data	1,015	1.1	0	24.9	0	1.4	1.4
Surface Mine Area	171	1.5	0	24.9	1.1	1.8	0.7
Main without Anomalous Area	791	1.0	0	9.0	0	1.3	1.3
Anomalous Area	53	1.4	0	2.3	0	1.8	1.8

5.1.2.2.3 Final Gamma Exposure Rate Mapping

The linear regression model correlating sodium iodide detector readings to PIC measurements predicts a site-wide average exposure rate of 10.9 µR/hr. The range of predicted exposure rates is 5.9 to 324 µR/hr, based on the observed gamma-ray count rates at the site. As indicated on Figure 5.1-7, predicted exposure rates ranging from 21 to greater than 75 µR/hr occur in the open pit mine areas, near the artesian well in Section 5 and its localized discharge areas, and in rocky outcrop areas in the northwest corner of the surface mine area. Predicted exposure rates in the anomalous area in the northern portion of the main PAA range from less than 12 to 30 µR/hr.

5.1.2.2.4 Soil Ra-226 Concentration Mapping

Predicted radium-226 concentrations in soil are shown as grid block averages on Figure 5.1-8. It is important to acknowledge that discrepancies between measured soil radium-226 concentrations reported by the laboratory and corresponding radium-226 concentrations estimated by gamma surveys are inevitable in a characterization survey of this nature and magnitude, given the heterogeneity of the site (at least in some areas) and differing detector-source geometry at various sample/survey locations.

At the same time, Figure 5.1-8 shows that without a gamma survey, reliance on a random soil sampling program alone would not have identified elevated areas of radioactivity at the site.

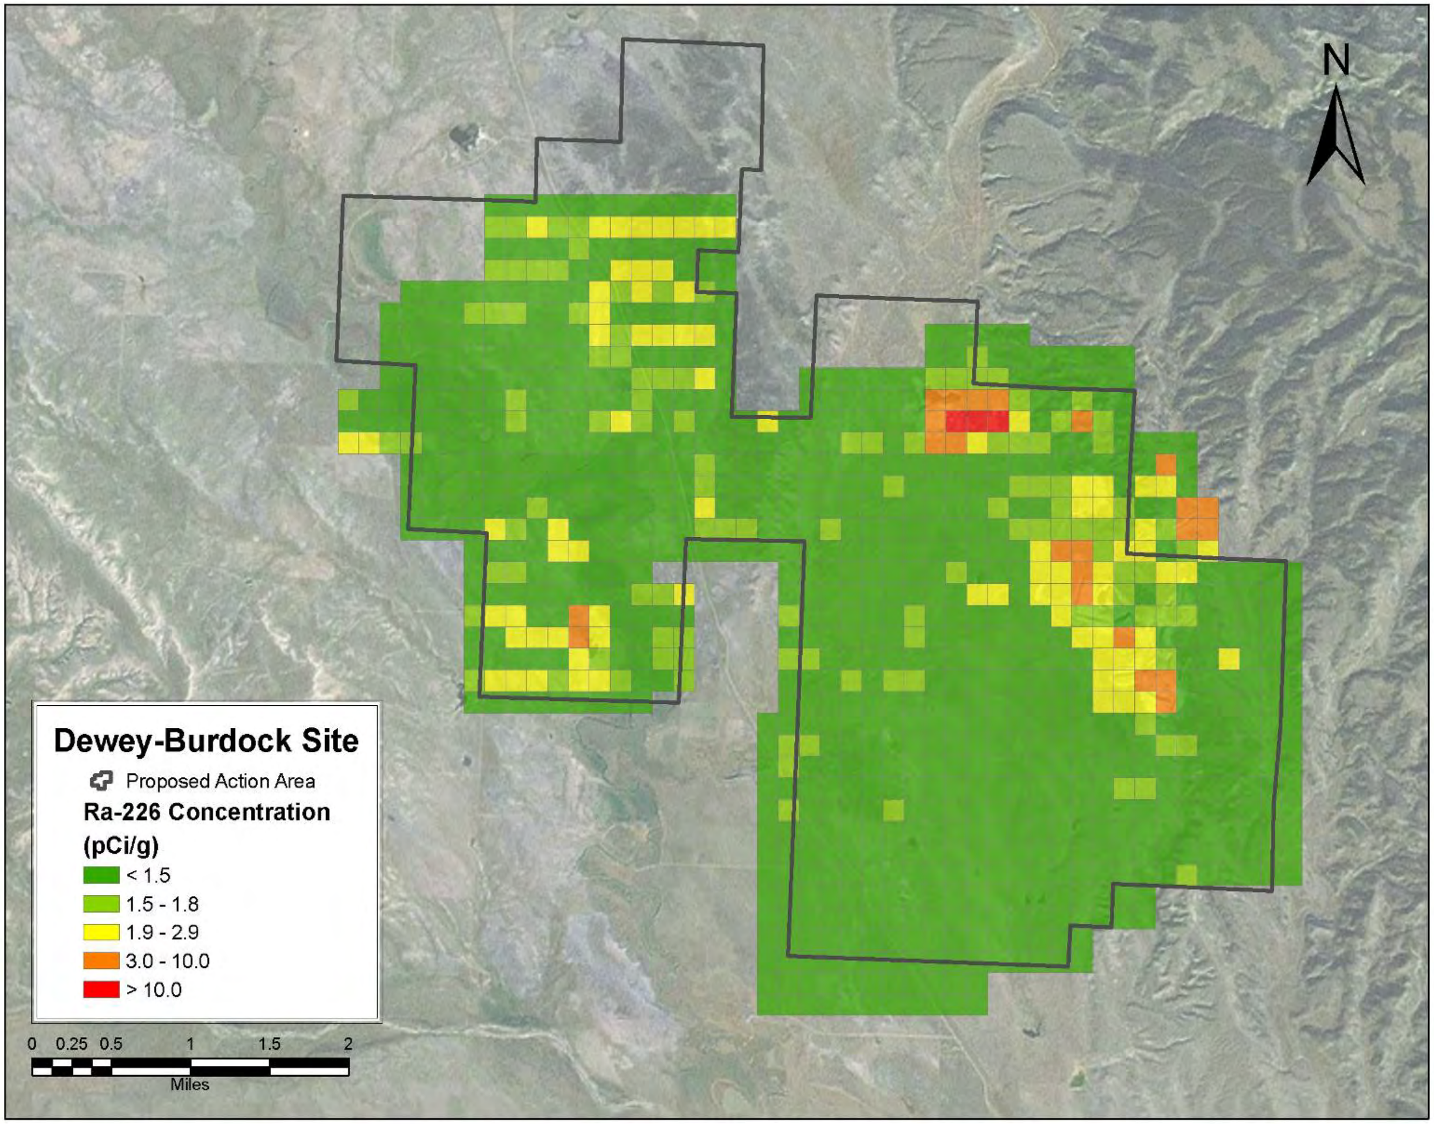

Figure 5.1-8 Predicted Site-Wide Radium-226 Concentrations, Grid Block Averages

5.1.3 Soil Sampling

5.1.3.1 Surface Soil Sampling

In the case of surface soil radiological characterization, sample placement prescribed by RG 4.14 was modified. RG 4.14 states that soil sampling locations start at a point halfway between proposed tailings and process areas, and 0-5 cm samples are collected every 300 m out to 1500 m in eight compass directions (40 samples) and one at each air monitoring station. This prescribed spacing largely ignores potentially varying site features such as soil types, drainages, outcrops, and the affects of historical activities. In addition, the soil sampling depth of 0-5 cm does not coincide with applicable cleanup standards. The NUREG-1569 requirements include collecting 0-15 cm samples to be consistent with the radium-226 cleanup standard of 5 pCi/g above background for the 0-15 cm soil horizon (10 CFR 40, Appendix A, Criterion 6(6)).

RG 4.14 suggests the collection of 40 samples from 0-5 cm and NUREG-1569 suggests the collection of samples at 0-15 cm. To avoid any ambiguity in the interpretation of these guidance documents, Powertech chose to collect 80 samples at 0-15 cm and supplementing the sampling effort with Global Positioning System (GPS)-based gamma radiation surveys. This sample size was determined to be adequate based on criteria in NUREG-1575. The GPS-based surveys allow orders of magnitude more data to be obtained with a similar effort. Owners of uranium recovery sites that have or are undergoing decommissioning are finding that extensive baseline data are invaluable. In conjunction with soil sampling and analysis and cross-reference to PIC measurements, the GPS-based gamma surveys can be used to predict site-wide concentrations of gamma-emitting radionuclides and/or exposure rates. Spatial trends in gamma emissions (and radionuclide concentrations as surrogates) are also far more apparent through the use of GPS-based gamma surveys than soil sampling alone. As will be shown below, reliance on a random soil sampling program alone would not have identified elevated areas of radioactivity at the site.

Main Permit and Surface Mine Areas

The soil sampling strategy for the main permit and surface mine areas of the project site consisted of biased and random sampling at the eight AMS locations shown in Figure 5.1-9 (this figure also shows the locations of the radon flux and track etch detector measurements, discussed below) and 80 additional locations shown in Figure 5.1-10. Biased samples were collected at five of the 80 locations; the remainder was placed randomly, using Visual Sampling Plan (VSP), Version 5.0. The biased samples were obtained in the surface mine area and selected to bound the upper range of radionuclide concentrations. The five biased samples are not sufficient to characterize radium-226 concentrations in impacted areas.

The additional 80 surface soil samples were collected from 0-15 cm below ground surface. Seventy-one of these samples were collected using a hand shovel. A hand auger was used to collect samples at 0-15, 15-30, and 30-100 cm at nine of the 80 locations. All of the soil samples were analyzed for radium-226. Ten of the 80 samples were also analyzed for natural uranium, lead-210, and thorium-230. Thirteen duplicate samples were collected: 11 with the surface set and 2 with the subsurface set. All duplicate samples were analyzed for radium-226 while two were also analyzed for natural uranium, thorium-230, and lead-210. The analytes and corresponding analytical methods were:

Radium-226 via gamma spectroscopy or radon emanation: EPA Methods 901.1 and 903.1, respectively. Prescribed Procedures for Measurement of Radioactivity in Drinking Water (EPA/600/4-80-032), August 1980. The majority of radium-226 analyses were performed using EPA Method 901.1.

Thorium-230: EPA 907.0 Prescribed Procedures for Measurement of Radioactivity in Drinking Water (EPA/600/4-80-032), August 1980.

Natural Uranium: EPA 6020 ICP-MS, Test Methods for Evaluating Solid Waste, Physical/Chemical Methods (SW-846), June 2007

Lead-210: EPA 909.0M Prescribed Procedures for Measurement of Radioactivity in Drinking Water (EPA/600/4-80-032), 1980.

Land Application Areas

To characterize baseline radionuclide concentrations in soils in the land application areas, samples were collected at 17 locations, 10 in the northern and 7 in the southern area, from three intervals: 0-15, 15-30, and 30-100 cm. Refusal was encountered at 10 inches below ground surface (bgs) in LAN-008 and the lower interval was not collected. The sample locations, selected randomly using VSP Version 5.0, are shown on Figure 5.1-11. The samples were analyzed for radium-226, natural uranium, thorium-230, and lead-210.

5.1.3.2 Soil Sampling Results

Table 5.1-5 presents the radium-226 concentrations in the soil samples collected in the main permit, surface mine, and land application areas. The results described in this section are those determined using only EPA Method 901.1. The laboratory analytical data reports are provided in Appendix 5.1-A.

Samples are identified as follows, with duplicates labeled as "Dup":

- AMS: air monitoring station
- SMA: surface mine area
- MPA: main
- NEA: northeast area
- RFA: roll front area
- LAN: land application area north (Dewey)
- LAS: land application south (Burdock)

5.1.3.2.1 Surface Soil Sample Results

Radium-226 Concentrations in the First Set of 80 Locations

In the set of 80 surface samples, the mean and median radium-226 concentrations are 2.9 and 1.3 pCi/g, respectively. Q1 and Q3 are 1.1 and 1.7 pCi/g, respectively. The IQR is 0.6. The mode is 1.1 pCi/g (12 observations). One result (0.45 pCi/g, Sample Location SMA-18) was a low outlier. Thirteen values exceeded 2.3 pCi/g, the cutoff for high outliers.

The soil data were fitted to normal and lognormal distributions. The p-values for both distributions are less than 0.005, indicating that at a 95 percent confidence level ($p = 0.05$), the distributions are non-normal and non-lognormal.

Considering that the data do not fit normal or lognormal distributions, and clear differences in the gamma-ray count rates obtained in the surface mine and main PAAs are indicative of differences in the levels of gamma-emitting radionuclides therein, the set of surface soil data was divided into surface mine and main PAA subsets, as discussed in the following sections.

Radium-226 Concentrations in the Surface Mine Area

Twenty-five surface soil samples were collected in the surface mine area. The data did not fit a parametric distribution. The median radium-226 concentration was 1.4 pCi/g. Five of the concentrations were outliers, exceeding a cutoff (1.5 times Q3) of 5.9 pCi/g. The outliers are the radium-226 concentrations in the five biased samples, all collected in the surface mine area.

The data set with the outliers removed fit a lognormal distribution. The central tendency and variability of a lognormal distribution are best represented by the geometric mean and geometric standard deviation, each of which is 1.3 pCi/g radium-226 in the case of the surface mine area data set. The data lie within a population range of 0.76 to 2.2 pCi/g.

Radium-226 Concentrations in the Main Area

Fifty-five surface soil samples were collected in the main PAA. The data did not fit a parametric distribution. The median radium-226 concentration was 1.3 pCi/g. Three of the concentrations were outliers, exceeding a cutoff (1.5 times Q3) of 2.6 pCi/g.

The data set with the outliers removed fit a lognormal distribution. The geometric mean and geometric standard deviation of the set of main PAA radium-226 concentrations are each 1.3 pCi/g. The data lie within a population range of 0.76 to 2.2 pCi/g.

Radium-226 Concentrations in the North Section of Main PAA

It was stated above that elevated gamma-ray count rates were observed in an approximately 600-acre area located at the north end of the main PAA. Considering that the elevated levels are likely due to relatively higher increased levels of one or more gamma-emitting radionuclides, radium-226 concentrations in soil samples collected from this area were evaluated.

Eight surface soil samples were collected in this area (MPA-R01, NEA-R02, NEA-R03, NEA-R04, NEA-R05, RFA-03, RFA-06, and RFA-17). One of these samples was considered an outlier of the main PAA data set (NEA-R05).

There are too few soil samples collected in this area to characterize it statistically. However, the gamma-ray count rates therein differ from the main PAA, with statistical significance.

Radium-226 Concentrations in the Proposed Land Application Areas

Radium-226 concentrations in surface soils in the land application areas are summarized as follows:

- Averaged 1.1 pCi/g and ranged from 0.7 to 4.4 pCi/g in both areas
- Averaged 1.3 pCi/g in the Dewey land application area

- Averaged 0.8 pCi/g in the Burdock land application area

The concentrations of surrogate radionuclides, uranium, lead-210, and thorium-230 concentrations are consistently lower in the Burdock than in the Proposed Dewey Land Application Area, indicating that the lower radium-226 concentration is not a laboratory artifact.

Discussion of Radium-226 Concentrations
Although the distributions of the main permit and surface mine area radium-226 concentration data sets are similar, the gamma-ray count rate distributions in these two areas differ, with statistical significance. The gamma-ray count rates observed in the anomalous portion of the main area also differ from the main area.

With outliers removed, both the surface mine and main area radium-226 concentration data sets fit a lognormal distribution. The geometric mean and geometric standard deviation of both data sets is 1.3 pCi/g. The data lie within a population range of 0.76 to 2.2 pCi/g. The mean of 1.3 pCi/g is representative of a general background value in the majority of the PAA surface soils. Exceptional areas include those in and around the artesian well discharge and historical open pit mines. At this time, radium-226 concentrations are not well characterized in the northern anomalous area in the main area and along the northwest edge of the surface mine area.

The range of radium-226 concentrations in the land application areas lies within the range of overall radium-226 concentrations, averaging 1.3 and 0.8 pCi/g in the Dewey and Burdock areas, respectively.

Other Radionuclides
Table 5.1-6 summarizes the analytical results for all samples analyzed for the extended suite of radiological parameters (all locations and depths combined). Although the sample number isn't sufficient to allow any definitive conclusions to be drawn regarding distributional characteristics or trends of non radium-226 parameters, a positive relationship between the concentrations of radium-226 and natural uranium, thorium-230, and lead-210 is apparent.

Notes:
All errors reported are ± 2σ.

Limits of Detection
A summary of the results with respect to reporting limits and minimum detectable concentrations (MDCs) is as follows:

- The radium-226, lead-210, and thorium-230 lower limits of detection (LLD) (reported as MDCs or reporting limits) in the NEA, MPA, RFA, and SMA soil samples were all $1*10^{-7}$ µCi/g.
- The natural uranium LLDs in the NEA, MPA, RFA, and SMA samples ranged from $1.7*10^{-8}$ to $2.0*10^{-8}$ µCi/g.
- None of the results NEA, MPA, RFA, and SMA samples were below their respective LLDs.
- The lead-210 LLDs for the LAN and LAS samples ranged from $1.9*10^{-6}$ to $3.8*10^{-6}$ µCi/g. In all but one case, the lead-210 results were lower than their respective LLDs.
- The radium-226 LLDs for the LAN and LAS samples ranged from $4.0*10^{-8}$ to $1.0*10^{-7}$ µCi/g. All of the LAN and LAS results exceeded their respective LLDs.
- The thorium-230 LLD for the LAN and LAS samples was $1.0*10^{-7}$ µCi/g. Results for 17 of the 53 (surface and subsurface) samples were reported below $1.0*10^{-7}$ µCi/g.
- The natural uranium LLD for the LAN and LAS samples was $7.0*10^{-9}$ µCi/g. All of the results exceeded the LLD.

The LLD recommended in RG 4.14 for natural uranium, thorium-230, radium-226, and lead-210 in soils is $2*10^{-7}$ µCi/g. The only case for which the guidance was not followed was the LLD for lead-210 in the LAN and LAS samples.

5.1.3.2.2 Subsurface Soil Sample Results
Table 5.1-6 lists the subset of subsurface biased samples that were collected at depth in the project roll front areas: RFA-B01, RFA-B02 RFA-B13 RFA-B15, RFA-B17, RFA-B21, RFA-B30, RFA-B36, and RFA-B37. The table also lists results obtained in subsurface samples collected in the two land application areas: LAN-001 through LAN-009 and LAS-001 through LAS-007.

5.1.3.2.3 Data Uncertainty
This section briefly summarizes the results of the quality control (QC) samples collected for the baseline soil sampling program. The results of this QC effort are documented in Table 5.1-7, which lists the errors and LLDs for each duplicate pair. Table 5.1-7 documents associated comparisons, presenting the corresponding RPD (in the case of natural uranium) and/or Replicate Error Ratio (RER) for each QC pair. The calculation of RPDs and RERs is a standard technique used to evaluate laboratory precision.

The RPD is calculated as follows:

$$RPD = \frac{|A-B|}{\frac{A+B}{2}}$$

Where A and B are the sample and duplicate results, respectively.

The RER is calculated as follows:

$$RER = \frac{|S - R|}{\sqrt{(Sx0.15)^2 + (E_s)^2} + \sqrt{(Rx0.15)^2 + (E_R)^2}}$$

Where S and are the sample and duplicate concentrations, respectively. E_S and E_R are the sample (E_S) and duplicate errors (E_R). The factor of 0.15 accounts for any inherent systematic error which cannot be quantified. The acceptance criteria are an RPD and RER of less than 40 and 1 percent for data above the MDC, respectively, as established in a QAPP (ERG 2006). This data set shows four cases where the RER for lead-210 was greater than 1 and five cases where the RPD exceeded 40. There are three cases where the RER and RPD for radium-226 are exceeded (two concurrently).

Table 5.1-7 Quality Control Analysis for Soil Samples

LAN-004B+Duplicate	15-30	15.0	**263.2**	-85.7	**60.0**	**2.5**	0.9	**4.2**
LAN-004C+Duplicate	30-100	14.3	-40.0	33.3	22.2	0.4	0.6	**1.4**

Notes:
The radium-226, lead-210, and thorium-230 LLDs were all $1*10^{-7}$ µCi/g. All results are greater than 5 times their respective MDC, with the exception of radium-226 in Sample Location SMA-B18-Dup.
The natural uranium LLDs ranged from $1.7*10^{-8}$ to $2.0*10^{-8}$ µCi/g.
None of the results were below their respective LLDs.
Bolded values are anomalous QC results.

The consequences of one radium-226 and three lead-210 results exceeding the acceptance criteria are minimal since in each case the concentrations are low. In addition, lead-210 largely has no impact when addressing the impact of the baseline radiological characteristics of the site and potential impacts from site operations.

There is close agreement for all other analytical results reported for each duplicate pair collected for all parameters. Overall, duplicate results are generally comparable for the majority of QC samples collected. Considering the low level of radioactivity observed in most of the QC pairs, the laboratory performance on blind duplicates is satisfactory.

5.1.3.3 Conclusions

Main Permit and Surface Mine Areas
Main permit and surface mine areas' subsurface radium-226 concentrations, ranging from 0.7 to 5.6 pCi/g, are comparable to those observed in the 0-15 cm surface samples in the samples. There is no apparent trend with depth.

Land Application Areas
Subsurface concentrations in the land applications can be summarized as follows:

- Radium-226 concentrations range from 0.4 to 4.1 pCi/g, with a median of 0.9 pCi/g.
- Radium-226 concentrations in the project land application area have a median of 1.0 pCi/g.
- Radium-226 concentrations in the project land application area have a median of 0.8 pCi/g.

The subsurface results in both land application areas are comparable to those observed in the 0-15 cm surface samples. There is no apparent trend with depth.

5.1.4 Sediment Sampling

In June and August of 2008, baseline sediment sampling was conducted at the proposed project site in accordance with NRC Regulatory Guide 4.14 (NRC, 1980), which requires stream sediment samples during both seasonal runoff and low-flow conditions and one sediment sample at each impoundment to characterize radionuclide content. Stream sediment samples were collected at the same locations at which surface water quality sampling sites were located: upstream and downstream sites on Pass Creek, Beaver Creek, and the Cheyenne River, and one site on each of two ephemeral drainages located within the proposed project boundary. Impoundment sediment samples were collected in the same impoundments at which surface water chemistry was sampled. Figure 5.1-12 and Table 5.1-8 provide sediment sampling locations.

Stream sediment samples were collected upstream and downstream sites on three primary streams (Pass Creek, Beaver Creek, and the Cheyenne River) and sites on two other ephemeral drainages.

Sediment samples were collected in June 2008 from 11 surface water impoundments located in the area. Impoundments primarily consist of stockponds but also include historical open pit mines within the proposed permit boundary. At the time of sampling, the majority of subimpoundments had water present. As indicated by NRC Regulatory Guide 4.14, a one-time sampling event is sufficient to document radiological conditions of surface water impoundment sediments.

5.1.4.1 Stream Sediments Sampling

At each location, four sediment sub-samples were collected with a plastic hand trowel to a depth of 5 cm each, along a transect spanning the width of the channel in areas where active sediment deposition was occurring. Prior to sampling at each site, the trowel was cleaned by rinsing with a liquid Alconox solution followed by a deionized water rinse. To represent the average radionuclide concentration across the channel, the four sub-samples were composited into a single sample. The composite sample was placed in a plastic zipper bag labeled with site ID, date, and time of collection, which was then placed into another plastic zipper bag and into a cooler with ice.

Samples were hand-delivered to ELI in Rapid City, SD along with the chain of custody forms. At the lab, samples were dried, crushed, ground, and thoroughly homogenized prior to analysis. All samples were analyzed for natural uranium, thorium-230, radium-226, and lead-210 by wet radiochemical methods.

5.1.4.1.1 Surface Water Impoundment Sediment Sampling

Sediment sampling locations for surface water impoundments were the same as the subset of impoundments selected for water quality analysis. Impoundments were identified on aerial photographs and topographic maps and then field verified (Figure 5.1-13). A subset of 11 of the total 48 impoundments within a 2 km radius of the proposed permit boundary were chosen based on presence of water at commencement of water-quality sampling activities and their spatial distribution. The sampled impoundments include two open pit uranium mines and nine stock dams, one of which is fed by a free-flowing artesian Sundance well.

At each of the 11 sampled impoundments, a single sample was collected with a trowel to a depth of 5 cm. Prior to sampling at each site, the trowel was cleaned by rinsing with a liquid Alconox solution followed by a deionized water rinse. Samples were collected near the waters edge in a location appearing relatively undisturbed. In dry impoundments samples were collected near the upstream side of the impoundment in an area that would be submerged if water was present. The samples were placed in a plastic zipper bag labeled with site ID, date, and time of collection, then placed into another plastic zipper bag and into a cooler with ice.

Samples were hand-delivered to ELI in Rapid City, SD along with the chain of custody forms. At the lab, samples were dried, crushed, ground, and thoroughly homogenized prior to analysis. All samples were analyzed for natural uranium, thorium-230, radium-226, and lead-210 by wet radiochemical methods.

5.1.4.2 Stream Sediment Sample Results

Results of the stream sediment data for each stream channel sampling location and impoundment location are provided in Table 5.1-9. Beaver Creek sediment sample results from the historical TVA survey (TVA EIS, 1980) are provided in Table 5.1-10.

5.1.4.3 Conclusions

The radionuclide concentrations in sediments at the project site are generally consistent with observed US soil concentrations (Myrick 1983). Exceptions are the Darrow Mine Pit (Sub 06) and the Triangle Mine Pit (Sub 02), both of which appear to contain radionuclide concentrations in sediments considerably higher than observed in soil by Myrick, 1983. The Darrow and Triangle Mine Pits are historical open pit uranium mines and elevated radionuclide concentrations in sediments would be expected.

Radionuclide concentrations in sediment at downstream locations of Pass Creek (PSC01) and the Cheyenne River (CHR05) are elevated compared to upstream locations for the same surface water bodies indicating potential impacts from disturbed and mineralized areas of the historic uranium mines on and adjacent to the site. Radionuclide concentrations in sediment at the downstream location on Beaver Creek (BVCO1) are similar to the upstream location (BVC04). The course of Beaver Creek through the PAA is entirely over the marine shales of the Graneros Group which do not contain uranium-bearing minerals.

5.1.5 Ambient Gamma and Radon Monitoring

5.1.5.1 Ambient Gamma Dose Rate Monitoring

Ambient exposure rates were determined for three periods using TLDs supplied and analyzed by Landauer, Inc. The monitoring periods were: August 18, 2007 to February 4, 2008, February 4 to May 17, 2008, and May 17 to July 17, 2008.
The TLDs were deployed at each of the eight AMS locations. Duplicates were deployed at AMS-01 and the background location (AMS-BKG).

Five of the nine TLDs deployed in the August 2007 to February 2008 period were lost, presumably by way of cattle consumption and/or disturbance.

5.1.5.1.1 Ambient Radon-222 Monitoring

Radtrak passive track etch detectors were placed at each of the eight AMS locations and an additional eight biased locations to measure radon-222 concentrations in air. For QC purposes, one duplicate detector was placed at each of two locations during each sampling event. The locations of the passive radon detectors are shown on Figure 5.1-9.

The detector measures average radon-222 concentrations in air over the measurement period. The results are reported in picocuries per liter (pCi/L).

A temporal overlap occurred across the group of detectors, but not on an individual location basis, the four quarterly measurement periods were as shown below in Table 5.1-11.

Table 5.1-11 Quarterly Measurement Periods

Period 1	August	14	2007	September	27	2007
Period 2	September	27	2007	February	1-12	2008
Period 3	February	1-12	2008	May	17	2008
Period 4	May	17	2008	July	17	2008

5.1.5.2 Results

5.1.5.2.1 Ambient Gamma Dose Rate Monitoring

The ambient gamma dose rate monitoring results are listed in Table 5.1-12. The results for the TLDs reported in mrem ambient dose equivalents are as follows:

- AMS-01: 94.9 for 303 monitored days, projected to 114 mrem/year
- AMS-02: 54.0 for 61 monitored days, projected to 323 mrem/year
- AMS-03: 38.6 for 103 monitored days, projected to 137 mrem/year
- AMS-04: 152.8 for 303 monitored days, projected to 184 mrem/year
- AMS-05: 123.7 for 303 monitored days, projected to 149 mrem/year
- AMS-06: 88.0, for 164 monitored days projected to 196 mrem/year
- AMS-07: 145.3 for 303 monitored days, projected to 175 mrem/year
- AMS-BKG: 167.8 for 303 monitored days, projected to 202 mrem/year

Excluding the result at AMS-02, the range of exposure rates, 114-202 mrem/year, is similar to average worldwide exposures to natural radiation sources comprised of cosmic radiation, cosmogenic radionuclides, and external terrestrial radiation reported in the United Nations Scientific Committee on the Effects of Atomic Radiation (UNSCEAR),2000 Report to the General Assembly, Sources and Effects of Ionizing Radiation, Annex B . The typical ranges of average worldwide exposures reported in this reference document are 60 to 160 mrem/year.

Ambient Radon-222 Monitoring

The ambient radon monitoring results are listed in Table 5.1-13. Period 1 ambient radon concentrations ranged from 1.0 to 9.8, averaging 2.4 pCi/L. Period 2 concentrations ranged from 0.4 to 1.8, averaging 1.2 pCi/L. Period 3 concentrations ranged from 0.4 to 3.3, averaging 1.8 pCi/L. Period 4 concentrations ranged from 0.5 to 0.8, averaging 0.5 pCi/L.

Notes: [a]Duplicate track etch detector
[a]Seal potentially compromised

With the exception of one location (AMS-3), Period 1 concentrations exceeded Period 2 concentrations. On average, the radon concentrations decreased by an average of 35 percent. The range in the data sets decreased from 2.1 (Period 1) to 0.3 pCi/L (Period 2), as the largest value in Period 1, 9.8 pCi/L, decreased to 1.2 pCi/L.

There are many factors to explain the variability. The most important are:

- Wind speed and direction
- Topography- Radon is heavier than air and will concentrate and flow down low areas and drainages on calm days.
- Soil moisture and ground cover influence the radon flux from the soil to the air
- Air temperature and barometric pressure
- Sources of radon such as mines

All these can influence the radon concentration at a given monitoring location and all are part of the baseline condition. To identify which of the above parameters specifically contributed to the observed variability would be speculative.

Figure 5.1-14 presents the ambient radon concentrations in relation to the radium-226 concentrations predicted from the gamma-ray count rate data. One expects higher radon concentrations in the mined areas. However, there is only one case where this is true: the Q1 observation at Rn-02, located adjacent to the edge of an open pit mine, is 9.8 pCi/L. There appear to be no spatial trends in the current data set, other than the levels are within the same order of magnitude across the site, i.e., all less than 10 pCi/L and averaging 2.4, 1.2, 1.8, and 0.5 pCi/L in Periods 1 through 4, respectively.

Duplicates were collected at AMS-01 and AMS-BKG in all periods. The QC summary for the radon monitoring is as follows:

AMS-01: In Period 1, each concentration was 1.0 pCi/L and the relative percent difference (RPD) was 0. In Periods 2 and 3, the concentrations of the sample and its duplicate were 0.7 and 0.4 pCi/L. The RPD was 55.5. In Period 4, each concentration was 0.49 pCi/L and the RPD was 0.

AMS-BKG: In Period 1, the concentrations of the sample and its duplicate were 2.0 and 2.7 pCi/L. The RPD was 29.8. In Period 2, the concentrations of the sample and its duplicate were 1.6 and 1.5 pCi/L, with an RPD of 6.5. In Period 3, the concentrations of the sample and its duplicate were 1.7 and 1.5 pCi/L, with an RPD of 12.5. In Period 4, the concentrations of the sample and its duplicate were 0.5 and 0.49 pCi/L, with an RPD of 0.7.

There are two cases where the RPDs do not meet the project acceptance criterion of 40: AMS-01 in Period 2 and 3.

Conclusions

In terms of effluent limits, the measured values exceed the 10 CFR 20 limit of 0.1 pCi/L for radon-222 with daughters present. However, on average the measured values are within the range of reported worldwide ambient background radon concentrations, 0.027 to 2.7 pCi/L (United Nations Scientific Committee on the Effects of Atomic Radiation [UNSCEAR], 2000).

Powertech (USA) Inc.

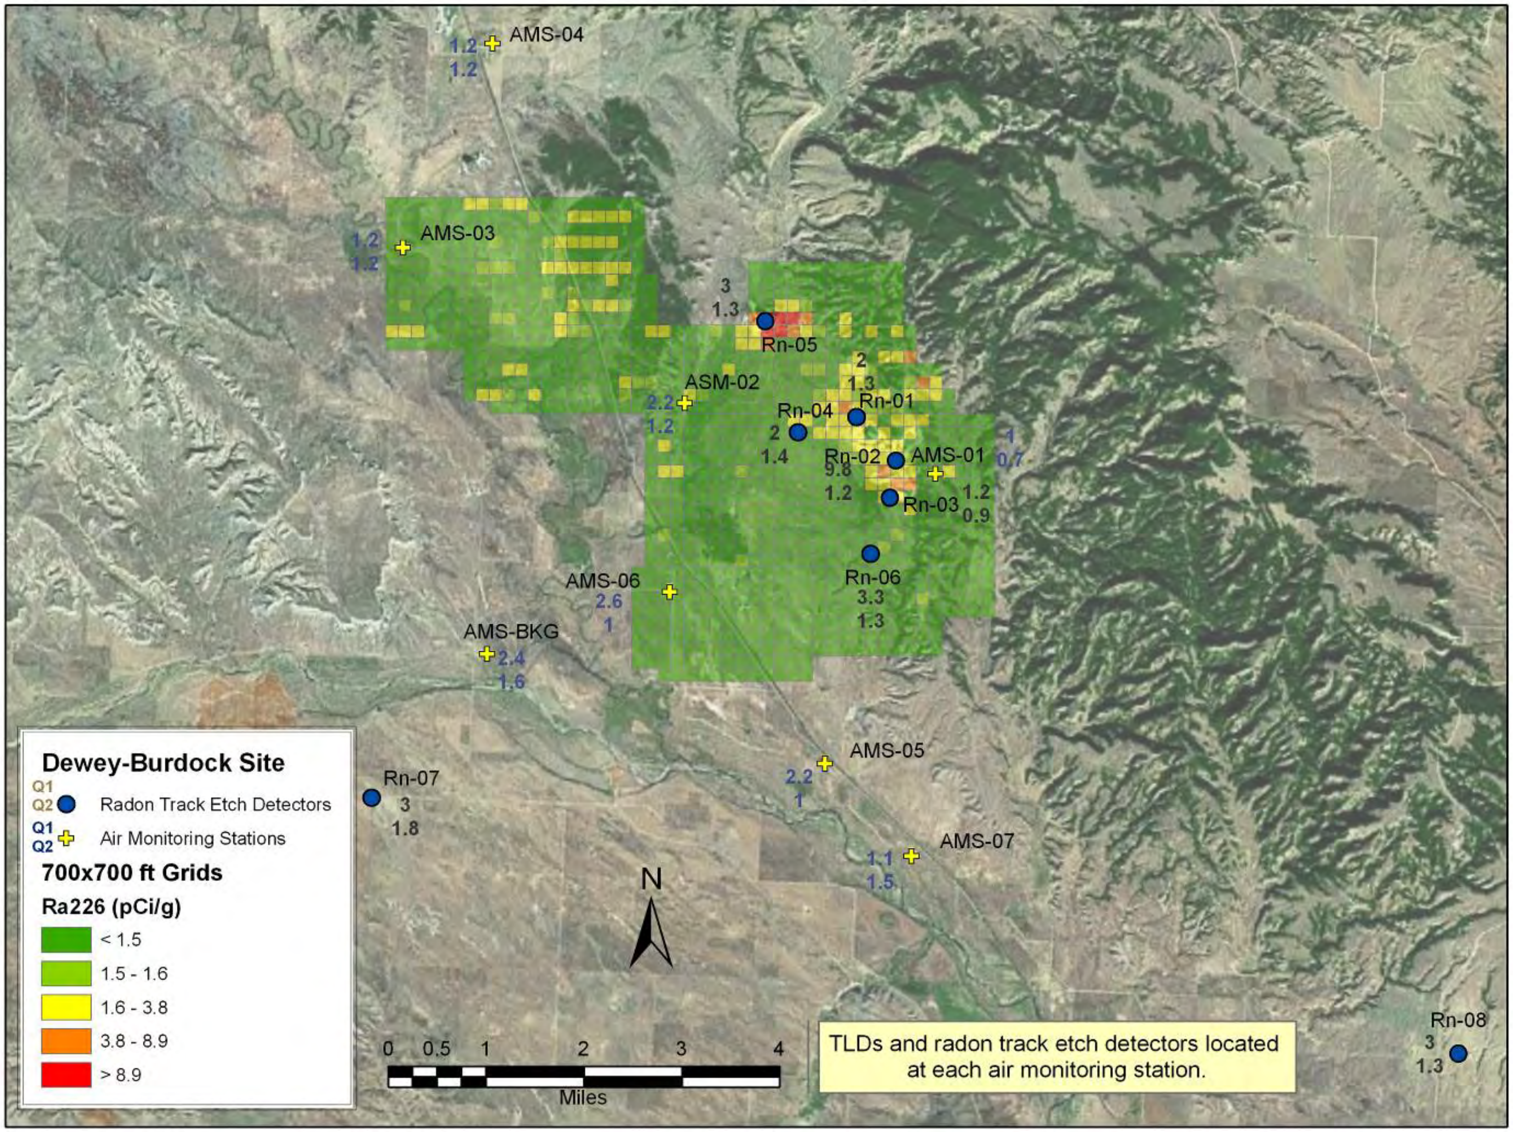

Figure 5.1-14 Radon Concentrations in Air in Relation to Predicted Radium-226 Concentrations

Air Particulate Monitoring
Air particulate monitoring was conducted at the project for one year. Particulates were collected using high volume air samplers.

Methods
Eight Hi-Q Model HVP-4200AFC high volume air samplers were established within and surrounding the proposed PAA. The samplers operated from August 2007 to August 2008. The locations of the air samplers are shown on Figures 5.1-9 and 5.1-14.

Each high volume air sampler was equipped with an 8-in. by 10-in. 0.8 micron glass fiber filter paper. The air filters were collected approximately bi-weekly, prior to saturation, from each of the eight air samplers. Flow rate and total flow data were recorded at the same time. The samples were collected as follows:

- Period 1: August 28 to October 2, 2007
- Period 2: October 2, 2007 to January 1, 2008
- Period 3: January 4 to April 1, 2008
- Period 4: April 1 to July 9, 2008
- Period 5: July 9 to August 13, 2008

The samples were composited and digested by the external independent analytical laboratory. The samples were analyzed for radium-226, thorium-230, natural uranium, and lead-210, using the same methods as listed for the soil samples.

The laboratory data were reported in units of picocuries per filter composite (pCi/f). The data were converted to units of microcuries per milliliter (µCi/ml), as follows:

$$Concentration,\ \mu Ci/ml = \frac{Filter\ Concentration}{Total\ Flow}(1*10^{-12})$$

The units of total flow and filter concentration in the equation are cubic meters and pCi/f, respectively. The resulting concentrations for each radionuclide and high volume sampler were compared to effluent concentration limits listed in Table 2 of 10 CFR 20 Appendix B and reported in Table 5.1-13 as percentages of the respective effluent limits. The most conservative effluent limits were applied to thorium-230 ($3*10^{-12}$ µCi/ml) and lead-210 ($6*10^{-13}$ µCi/ml). The Class D and W limits were applied to natural uranium ($3*10^{-12}$ µCi/ml) and radium-226 ($9*10^{-13}$ µCi/ml), respectively.

Air Particulate Sampling Results
In general and relative to one another (e.g., natural uranium to radium-226), the average concentrations of radionuclides were consistent at each location from period to period. The lowest average concentration was radium-226, followed by thorium-230, natural uranium, and lead-210. Average radium-226 concentrations were five orders of magnitude lower than lead-210 concentrations. The data are listed in Table 5.1-14 and summarized as averages and ranges in Table 5.1-15.

Site-wide, the data can be summarized as follows:

- Natural uranium concentrations ranged from $-3.0*10^{-17}$ to $9.1*10^{-15}$ µCi/ml and averaged $7.5*10^{-16}$ µCi/ml.

- Thorium-230 concentrations ranged from $-9.5*10^{-19}$ to $5.6*10^{-17}$ µCi/ml and averaged $1.2*10^{-17}$ µCi/ml.
- Radium-226 concentrations ranged from $-4.9*10^{-17}$ to $4.7*10^{-17}$ µCi/ml and averaged $8.9*10^{-19}$ µCi/ml.
- Lead-210 concentrations ranged from $-1.1*10^{-16}$ to $4.1*10^{-14}$ µCi/ml and averaged $1.4*10^{-14}$ µCi/ml.

There are no clear patterns in the data, in terms of radionuclide concentrations, when evaluating them spatially or temporally. Natural uranium concentrations at each location were on the order of 10^{-16} µCi/ml over the course of monitoring. Thorium-230 concentrations fluctuated between the orders of 10^{-17} and 10^{-18} µCi/ml. Radium-226 concentrations fluctuated between the orders of 10^{-17} and 10^{-19} µCi/ml. Finally, lead-210 concentrations at each location were all on the order of 10^{-14} µCi/ml over the course of monitoring.

Notes: The laboratory reported no blank assay data for Period 5. Blank assays in the sample concentration calculation were assumed to be 50 percent of the values for blanks reported for the previous period. The assumption is based on the relative, approximate run-time of the air samplers in both periods; NR = Not reported by the laboratory.

Table 5.1-15 Summary of Radionuclide Concentrations in Air

AMS-BKG	5.9E-16	1.3E-15	-8.1E-18	3.0E-15	1.5E-17	1.3E-17	-7.8E-19	2.8E-17	-2.5E-18	1.1E-17	-1.7E-17	1.2E-17	1.4E-14	1.2E-17	9.5E-18	4.0E-17

In terms of comparison to 10 CFR 20 Appendix B effluent limits, the data can be summarized as follows:

- Natural uranium concentrations were 0.0 to 0.3 percent of its effluent limit.
- Thorium-230 concentrations were 0.0 percent of its effluent limit.
- Radium-226 concentrations were -0.01 to 0.01 percent of its effluent limit.
- Lead-210 concentrations were -0.02 to 6.78 percent of its effluent limit.

The LLDs, in pCi/f, reported by the laboratory for each radionuclide were converted to µCi/ml by multiplying pCi/f by $1*10^{-12}$. In no cases were the LLDs higher that their respective 10 CFR 20 effluent concentration limits. The LLDs reported in Period 2 by the laboratory for uranium exceeded the recommendation in NRC Regulatory Guide 4.14.

The LLDs for each of the radionuclides are listed in Table 5.1-14.

Conclusions
With the exception of natural uranium, the values determined above are similar to U.S. background concentrations reported in the UNSCEAR Report to the General Assembly, Sources and Effects of Ionizing Radiation, Annex B. The regional concentrations reported in this reference document are: uranium-238 ($2.4*10^{-17}$ to $1.4*10^{-16}$ µCi/ml), thorium-230 ($1.6*10^{-17}$ µCi/ml), radium-226 ($1.6*10^{-17}$ µCi/ml), and lead-210 ($2.7*10^{-15}$ to $2.7*10^{-14}$ µCi/ml).

Radon Flux Measurements
Radon flux rates were measured at nine locations on three occasions in the Dewey and Burdock roll front areas. The locations are shown on Figure 5.1-9. The locations coincide with the nine soil samples collected from 0-100 cm below ground surface (not in land application areas).

The first round of flux canisters was deployed on September 26, retrieved on September 27, and analyzed on September 28, 2007. The second round of flux canisters was deployed on April 20, retrieved on April 21, and analyzed on April 22, 2008. The third round of flux canisters was deployed on July 14, retrieved on July 15, and analyzed on July 16, 2008. The canisters were analyzed using EPA Test Method 115, Monitoring for Radon-222 Emissions. Results are documented in the Table 5.1-16. Sampling for the three periods yielded flux rates of 1.22, 0.74, and 1.5 picocuries per meter squared second (pCi/m^2-s), respectively. Flux rates ranged between 0.68 and 1.77 pCi/m^2-s in fall 2007, 0.28 and 1.33 pCi/m^2-s in spring 2008 and 0.48 and 2.38 pCi/m^2-s in summer 2008.

Table 5.1-16 Baseline Radon Flux Measurements

	April 2008	1.33	0.06	0.16	
	July 2008	1.27	0.05	0.14	

Conclusions

The flux rates determined at the PAA are one to two orders of magnitude below the National Emissions Standards for Hazardous Air Pollutants (NESHAPS) requirements of 20 pCi/m²-s specified in 10 CFR 40, Appendix A, Criterion 6. Although the latter requirement applies to tailings and thus is not directly germane to this characterization, it is useful as a context to demonstrate the relatively low magnitude of baseline radon flux rates measured at the site.

5.1.6 Groundwater Sampling

TVA sponsored a groundwater sampling investigation within the Burdock area, in support of a Draft Environmental Statement (DES) in order to quantify groundwater quality within the Edgemont Uranium Mining Project area. The investigation was conducted over the one year period of November 1976 through November of 1977. The groundwater data represents the Fall River and Lakota Formations that form the Inyan Kara Group.

In summary of the investigation a brief discussion is provided in support of current groundwater quality data:

Historic TVA Sampling

The TVA groundwater investigation observed the water from Fall River and Lakota intermixed within some of the wells, thus representing a composite sample of the two formations. Dissolved solids averaged 1,000 mg/L and rated very hard; principle cations for both formations of the Burdock area were observed to be calcium and sodium; principle anions were sulfate and bicarbonates. Concentrations of dissolved solids, sulfates, iron and manganese exceeded the EPA secondary water quality standards. Lead exceeded the EPA standard (1,600 g/L) in one non-flowing well.

PA Baseline Sampling

At the project site, baseline groundwater sampling was conducted in general accordance with NRC Regulatory Guide 4.14 (NRC, 1980). Because of the significant number of groundwater wells, their geochemical similarities, and an abundance of historical water quality data, a representative subset of the wells was selected for sampling. The wells were selected based on type of use, aquifer, and location in relation to the ore bodies. The baseline study for the NRC license application consisted of 19 groundwater wells (14 existing and 5 newly drilled) making up a representative sampling group for the area (Figure 5.1-15, Table 5.1-17). The wells selected for sampling include eight domestic wells, six stock watering wells, with three of the 14 existing wells being hydrologically upgradient of the proposed recovery areas. The total number of wells chosen for site characterization of the groundwater includes wells within the Fall River Formation (4), Lakota Formation (7), Inyan Kara Group (Fall River or Lakota) (2), Sundance Formation (1), and alluvium (5). Initial baseline sampling of these wells was conducted quarterly, from July 2007 through June 2008.

As required by the SD DENR (rule ARSD 74:29), an additional 12 wells were sampled monthly beginning in March 2008 and continued through February 2009 for a final total of all wells sampled of 31. The 12 wells required by DENR are represented in (Figure 5.1-16 and Table 5.1-18). Of the 12 wells, six wells are located in the Dewey area and six wells are located in and near the Burdock area. Of the Dewey wells, there is a set of Fall River and Lakota wells sampled, upgradient of, within the PAA, and down gradient of proposed production activities. Near the Burdock area, the same well arrangement applies with two wells upgradient of, two wells within the proposed production area, and two downgradient of the proposed production area. Data for radiological parameters available to date are presented in this section.

Methods

Static water levels were measured at most wells prior to sample collection with regard to a reference elevation, usually a mark on the well or on a permanent structure above or near to the well. When possible, pressure of artesian wells was measured with a 15 psi or 30 psi N.I.S.T. – certified pressure gauge; the well was shut in and the pressure was allowed to stabilize before a reading was recorded. Pressure values were recorded to within at least one tenth of a psi and typically to within a hundredth of a psi. Wells with subsurface water levels were measured using an electric water level tape with measurements reported to within at least one tenth of a foot and typically to within a hundredth of a foot.

Exceptions to this were domestic wells that could not be accessed at the well head or were behind a pressure tank (wells 7, 8, 13, 16, 18, 42), free-flowing wells that could not be sealed due to leaks caused by corrosion and age (wells 2, 635, 4002), free-flowing wells that could not be sealed due to poor valve fittings or cracked valves (well 696), free-flowing wells where existed the possibility of rupturing a line when pressurized due to age (well 7002), and wells that contained pumps and pump tubing making it difficult to retrieve a water level tape (well 619).

All pumped wells, with the exception of 631, had permanent pumps installed in order to obtain samples. An existing high-capacity pump in well 631, used to pump water up a hill several hundred feet to a stock tank, was not used for sampling purposes due to logistical hurdles except for the first sample collected there on September 27, 2007. For the next three samples, a small dedicated pump was used each time the well was sampled.

Continuous free-flowing wells were sampled before pressure measurements were made and were not purged before sampling. For these wells (2, 18, 42, 635, 4002, 7002), it was assumed that free-flowing well water adequately represented formation water. After collecting a sample, a spot check with a water-quality probe was made and temperature, specific conductivity, turbidity, and pH were recorded. Pressure was then measured at the wells where it was possible within limits of feasibility.

After measuring the pressure of capped free-flowing wells (where possible), the well valve was opened and the flow rate was allowed to stabilize, then flow measurements were made using a stopwatch and a marked container (usually a 5-gallon pail, but sometimes a 1-gallon container at slower-flowing wells). Casing purge time was calculated based on water column height, casing diameter, and flow rate. Three well volumes were required to have been purged before the well water was sampled. Additionally, a water-quality sonde with a flow-through cell was connected to the well and. water quality parameters (pH, temperature and conductivity) were periodically recorded If parameters had not stabilized after purging three volumes, wells were allowed to continue to purge until parameters had stabilized, or until the purged volume was >> three well volumes.

Pumped wells were purged of three pore volumes and once one or more of the water quality parameters stabilized (conductivity, temperature, and pH) flow from the formation was sampled.

After measuring water level (where possible), the pump was started and flow rate was measured using stopwatch and 5-gallon marked pail.

A water-quality probe equipped with a flow-through cell was connected to outflow.

Wells with a high enough yield were purged for a minimum of three well volumes, and also until one or more indicator parameters had stabilized. Parameters monitored for stabilization were specific conductance, temperature, and pH. Field measurements were recorded periodically during purging of 3 volumes, and at least 3 minutes apart after purging three volumes. Table 5.1-19 provides requirements for parameter stabilization. After three well volumes had been purged and parameters stabilized, a sample was collected.

Wells that had yields too low to be continuously pumped and purged of three well volumes were pumped dry and allowed to recover. After the well had sufficiently recovered, it was pumped and sampled. Accurate records of well purging are maintained to document the number of casing volumes purged from the well before sampling, but in all cases a minimum of one casing volume was purged before sampling.

After calculating casing volume, alluvial wells were purged of three well volumes into a 5-gallon marked pail using either disposable bailers or a peristaltic pump. When using bailers, water quality parameters were recorded after each well volume was purged using a water-quality probe. When using the peristaltic pump, a water quality probe equipped with flow-through cell was connected to pump outflow and parameters (pH, temperature and conductivity) were recorded periodically during the purge.

Table 5.1-19 Stability Criteria for Collecting Groundwater Samples at Pumped Wells

Field Measurement	Stability Criteria[1]
pH	+/- 0.1 standard units
Temperature	+/- 0.2 C
Specific conductivity	+/- 5% (SC <= 100 µS/cm); otherwise +/- 3%

[1]Allowable variation between 5 or more sequential field-measurement values

Additional steps taken during water quality sampling include the following:

- Sampling procedures required a qualified technician (wearing gloves) to label each sample bottle with site ID, date, time of sampling, triple rinsing the bottle with sample water, then filling and capping it.
- Radon sample bottles were filled and capped immediately and with no headspace.
- Field replicate samples, consisting of a second set of samples collected at the same time following the same protocols as the sample set, were collected periodically to determine data accuracy.
- Field blanks were collected by transporting deionized water supplied by the contract laboratory to the field during regular sampling, then transferred to collection bottles in the field in order to subject the blank water to the same transportation, handling, storage, and field conditions as regular samples.
- All samples were immediately placed in coolers on ice after collection.
- Water quality sondes used to collect field parameter measurements were calibrated periodically using N.I.S.T.-traceable standards.

A groundwater quality constituent list was developed based on NUREG-1569 groundwater parameters, NRC 4.14 parameters, and added parameters from a constituent-list review with SD DENR.

Groundwater Sampling Radiological Results

Results to date for dissolved radiological groundwater parameters are shown in Table 5.2-20 and Table 5.2-21.

5.2 Groundwater

5.2.1 Regional Groundwater Use

The PAA is located at the southwestern edge of the Black Hills. The major aquifers of the Black Hills are the Inyan Kara, Minnelusa, Madison and Deadwood (see Section 7.8.1). Within Fall River and Custer Counties, each of these aquifers is used, with wells generally being drilled into the next underlying aquifer below the surface. There is no public data available to quantify the use from each of these aquifers within Fall River or Custer County.

5.2.2 Site Area Groundwater Use

In the PAA, the Fall River and Lakota Formations, together forming the Inyan Kara aquifer, are the principal sources of water. An inventory of private water-supply wells within an approximate 2 km radius of the proposed permit boundary was conducted in June 2007, during which about 80 wells were located (see Appendix 5.2-A). Most wells within 2 km of the site serve as water supply for livestock (26), although some wells are used for domestic (10) or other purposes (47) including piezometers, mine dewatering wells, and garden watering.

Wells within 2 km of the site include 24 wells known to obtain water from the Fall River Formation, with 12 of these wells being flowing artesian wells. Based on measurements from flowing wells and estimates from others, an estimated 15 gpm is currently being consumed from the Fall River. Within this same 2 km radius, there are 39 wells currently obtaining water from the Lakota Formation, 14 of which are flowing artesian. The estimated flow from these Lakota wells is 46 gpm. Additionally, 10 wells are completed within an unknown formation of the Inyan Kara aquifer (Fall River, Lakota, or both). The total estimated flow from the Inyan Kara (including wells screened within the Fall River, Lakota, or both) within 2 km of the site is approximately 70 gpm. There are six wells completed in the Sundance/Unkpapa, with four that are flowing. Within 2 km, an additional eight wells are completed into an unknown aquifer. Wells within the PAA that are currently in use are shown on Figure 5.2-1. Twenty-six wells in the vicinity of the PAA were deemed abandoned because of the condition and inactivity of the well; these wells termed abandoned are not considered properly plugged and abandoned (Figure 5.2-2).

Well completion reports and other related data are found in Appendix 5.2-B.

5.2.3 Regional Hydrology

Five major aquifers are utilized as groundwater resources in the Black Hills. These main aquifers are the Inyan Kara, Minnelusa, Madison, and Deadwood. The groundwater hydrology is influenced by distribution and variation in recharge, leakage between overlying and underlying hydrogeologic units, lateral flow within the aquifers, and discharge to pumping wells, artesian wells, and springs.

Regionally, the general direction of groundwater flow is downdip or radially away from the central part of the Black Hills where the aquifers are recharged via infiltration from local rainfall. The aquifers transition from unconfined at the outcrop areas to confined away from the central highlands. At some distance away from the highlands the groundwater often is under sufficient pressures for artesian conditions and flowing artesian wells to exist.

Figure 5.2-3 provides an overview of the hydrologic setting and general hydrogeologic flow within the Black Hills. See Section 7.8.1 for description of hydrostratigraphic units.

5.2.3.1 Groundwater Quality

This section presents a summary of analyses of recent groundwater quality samples, field measurements, laboratory results. Complete groundwater quality data results are available in Appendix 5.2-C. A number of parameters in the groundwater samples collected at the PAA exceeded the National Primary Drinking Water Standards. Constituents with samples exceeding the standards include arsenic, lead, uranium, radium-226, and gross alpha particles.

5.2.3.2 Field Parameter Results

Results of the groundwater field data gathered during well sampling activities are presented below. Table 5.2-1 gives summary statistics for temperature, dissolved oxygen, specific conductivity, pH, and turbidity for all field data. Tables 5.2-2 and 5.2-3 give field parameter statistics for Lakota, Fall River, and Inyan Kara wells where samples were collected monthly and quarterly, respectively. Table 5.2-4 gives field parameter statistics for alluvial well samples. A comparison of pH and specific conductance values for field and laboratory measurements reveals that laboratory results are within reasonable limits. Most pH values taken in the field are within a few hundredths to few tenths of a pH unit from that measured in the laboratory. For example, the highest pH recorded was 12.67 during sampling of Fall River well 691 on July 1, 2008. The high pH value was verified by the contracting laboratory which reported a pH of 12.4 in the sample. (This represents extremely alkaline water far outside the typical range of groundwater pH. Based on drill core, beds of the Fall River Formation in this area can be extremely well cemented with calcite.)

In the field, a maximum specific conductance of 12,220 uS/cm was measured at alluvial well 677 on September 28, 2007. The laboratory measured a specific conductance of this sample of 11,000 uS/cm. It is important to note that the laboratory conductance is given for the sample at 25°C and at the time of field measurements, the temperature of nearly every sample was much lower.

Table 5.2-1 Statistics for all Field Parameters Collected During Well Sampling Activities

	Temperature, C	pH	Dissolved Oxygen, mg/L	Specific Conductance, uS/cm	Turbidity, NTU
N	156	165	99	169	136

5.2.3.3 Laboratory Parameter Results

Summary statistics for baseline monitoring program laboratory samples are contained in Appendices 5.2-D and 5.2-E. Appendix 5.2-D gives statistics for all groundwater constituents detected at or above PQL by constituent. Appendix 5.2-E gives the minimum and maximum value for all sampled constituents detected at or above the PQL, and the site ID and date of the sample that had minimum and maximum detection value. Complete laboratory analytical results for each well are provided in Appendix 5.2-C.

5.2.3.3.1 Comparison of Site Baseline Water Quality to Drinking Water Standards

US EPA and South Dakota Primary Drinking Water Standards

Table 5.2-5 gives current National Primary and Secondary Drinking Water Standards as regulated by EPA. Also listed is the number of samples analyzed for each constituent, the total number of detections above the reporting limit, and the total number of detections equal to or above the Maximum Contaminant Level (MCL) for each constituent. These standards or MCLs are enforced by the EPA on public drinking water systems but can only serve as a guide for private water systems. Private water systems, as defined by the EPA, serve less than 25 people and have less than 15 service connections; all other systems are defined as public water systems. All drinking water wells within the PAA are private water systems.

As of August 24, 2004 all of the South Dakota Drinking Water Standards rules (ARSD 74:04:05) and Public Notice rules (ARSD 74:04:06) were repealed. In their place is ARSD 74:04:12. This new rule adopts by reference the latest published version of the Code of Federal Regulations (40 CFR Part 141), making South Dakota drinking water standards the same as EPA Primary Drinking Water Quality standards (Table 5.2-5).

Table 5.2-5 Sampling Statistics with Water Quality Regulatory Limits for Public Drinking Water Supply Systems

Test Analyte/Parameter	Units	EPA Maximum Contaminant Level (MCL)	Number of Samples Analyzed*	Number of Detections	Number of Detections equal to or above MCL

Radon-222 (total)	pCi/L	300 [5]	121	121	105

Notes: [1] "Secondary" guideline value above which use of water may give rise to complaints by consumers; [2] Health Advisory-Lifetime; [3] Action level which if exceeded triggers treatment; [4] Region 8 Permit Limit; [5] Proposed MCL; N/A – Not available
* Number of samples includes results for only those wells that were sampled quarterly or monthly as part of the baseline sampling plan.
**Number of samples analyzed under trace metals is based on samples that were analyzed for total trace metals.

5.2.3.3.2 Exceedances of Primary Drinking Water Standards

A number of groundwater samples collected at the PAA exceeded the National Primary Drinking Water Standards. Constituents with samples exceeding the standards include arsenic (Table 5.2-6), lead (Table 5.2-7), uranium (Table 5.2-8), radium-226 dissolved, suspended, and total (Tables 5.2-9 to 5.2-11), and gross alpha particles (Table 5.2-12); these tables provide constituent concentrations, well ID, and sample date for regulated constituents detected at or above MCL levels.

As shown on the table, nearly 75 percent of the samples exceeded the MCL for gross alpha particles (15 pCi/L), with the exceedances occurring in samples from the Inyan Kara aquifer and alluvial aquifer. The range of gross alpha particles in alluvial wells was 13.3 to 129 pCi/L. The range of gross alpha particles in Inyan Kara wells was 1.4 to 6500 pCi/L. Two of the three wells (680 and 681) having gross alpha concentrations over 1000 pCi/L are known to be directly within an ore body. The third is downgradient of open pit mines within the Fall River Formation.

Each sample collected from wells 615 and 3026 exceeded the MCL for arsenic. Also, half of all uranium exceedances are from alluvial aquifer samples.

5.2.3.3.3 Exceedances of Other Drinking Water Standards

In addition to primary drinking water standards established by the EPA, there are also a number of constituents (including radon-222) that have proposed standards which have not yet been adopted. Secondary drinking water standards (SMCL) set by the EPA are designated for constituents that alter the color, taste, and odor of water; these constituents are not considered health risks but may deter human consumption. These constituents, along with the number of samples that exceed these guidelines, are presented in Table 5.2-5.

Bulk water quality properties with SMCLs include pH and TDS. For samples collected as part of the baseline study, six wells exceeded the SMCL for pH with values ranging from 8.6 to 10.3. All of the samples exceeded the recommended concentration of TDS. Values of TDS ranged from 670 to 9700 mg/L with the highest values obtained from alluvial well samples.

A number of samples also exceeded the SMCL for sodium and sulfate. A total of 63 samples exceeded the secondary standard for sodium with values ranging from 201 to 2140 mg/L. The highest values of sodium were again from alluvial well samples. To date, all 141 samples exceeded the SMCL for sulfate of 250 mg/L; 86 of these samples were over double the limit (over 500 mg/L), and 59 samples were over 1000 mg/L sulfate. Fourteen samples had concentrations of sulfate over 3000 mg/L, all of which were from the alluvial aquifers.

Exceedances were noted for trace metals including boron, iron, manganese, and strontium. The three exceedances for boron were all collected from well 678 with values from 1.4 to 1.6 mg/L. Nearly half of the samples collected exceeded the SMCL of 0.3 mg/L for iron; 16 samples exceeded the Region 8 limit of 5.0 mg/L. The only water supply wells exceeding the Region 8 limit for iron are stock wells 619 and 650. The SMCL for manganese was exceeded by 89 of 98 samples; the Region 8 limit of 0.8 mg/L was exceeded by 19 samples. Values of manganese over the secondary guideline range from 0.05 to 3.4 mg/L. Strontium was exceeded in 37 of 98 samples analyzed with values ranging from 4.2 to 11.6 mg/L. The alluvial wells had the highest values for SMCL exceeded trace metals including boron, iron, manganese, and strontium.

South Dakota has recently adopted the proposed EPA MCL of 300 pCi/L groundwater standard for Radon-222. Of the 121 samples analyzed for Radon-222 as part of the Proposed Action baseline sampling program, 105 samples exceed the recommended level. Values of samples exceeding the limit range from 304 to 462,000 pCi/L. Thirty-six samples have over 10 times the recommended concentration of radon-222; 20 of these samples are over 100 times the proposed MCL. The wells with the highest concentration include wells 680 and 681, which are directly in a known ore body, and well 42, a private well used for domestic and stock water. The only well not exceeding the radon-222 limit is well 650, a Lakota well upgradient of historic uranium mining activities.

5.3 Surface Water

The Upper Cheyenne River basin extends through three states – Wyoming, Nebraska, and southwestern South Dakota (HUC No. 10120106, 10120107, 10120108). Within these states the Cheyenne River basin, above Angostura Reservoir in South Dakota, drains an area of approximately 8,996 square miles (mi^2) (Beauvais, 2000). The northern and central portions of the watershed are in the Black Hills division of the Great Plains and the southern portion is in the Pierre Hills division of the Great Plains (Kalvels, 1982 and Ensz, 1990). Land elevation ranges from about 3,160 feet (963 meters [m]) to 7,015 feet (2,138 m) above mean sea level.

5.3.1 Drainage Basins

The PAA lies primarily within the Beaver Creek Basin and is drained by both Beaver Creek and Pass Creek. The Pass Creek watershed is a sub-basin within the Beaver Creek basin, but the two watersheds were characterized as separate basins. The Beaver Creek system flows through the northwestern section of the PAA from the northwest to the southeast. The Pass Creek system flows south through the central portion of the PAA and joins Beaver Creek southwest of the PAA. Three miles south of this confluence, Beaver Creek converges with the Cheyenne River (Figure 5.3-1) which eventually flows into the Missouri River.

The nearest discharge gage on the Cheyenne River upstream of its confluence with Beaver Creek is USGS gage 06386500 near Spencer, WY. The nearest discharge gage downstream of the confluence of Beaver Creek and the Cheyenne River is USGS gage 06395000 at Edgemont, SD. This gage captures the contribution of flow to the Cheyenne River from Beaver Creek and Pass Creek between Spencer, WY and Edgemont, SD. Figure 5.3-2 shows an annual hydrograph for gage 06386500 from 1948 to 2008, and Figure 5.3-3 shows an annual hydrograph for gage 06395000 from 1903 to 2008. The lines in Figures 5.3-2 and 5.3-3 indicate the upper bound flow values for the 25th, 50th, and 95th flow percentiles for each of the 365 days per year. For example (in Figure 5.3-3), ased on all of the January 1st flow values during 1903 to 2008 (106 data points), the flow was less than 1 cfs on 25 percent of those days (26 days), less than 4 cfs on 50 percent of those days (53 days) and less than 30 cfs on 95 percent of those days (101 days). Therefore, the graph indicates how variable the stream flow tends to be at various times during the year (e.g., more variable during a typical July than a typical November).

![Powertech (USA) Inc. logo]

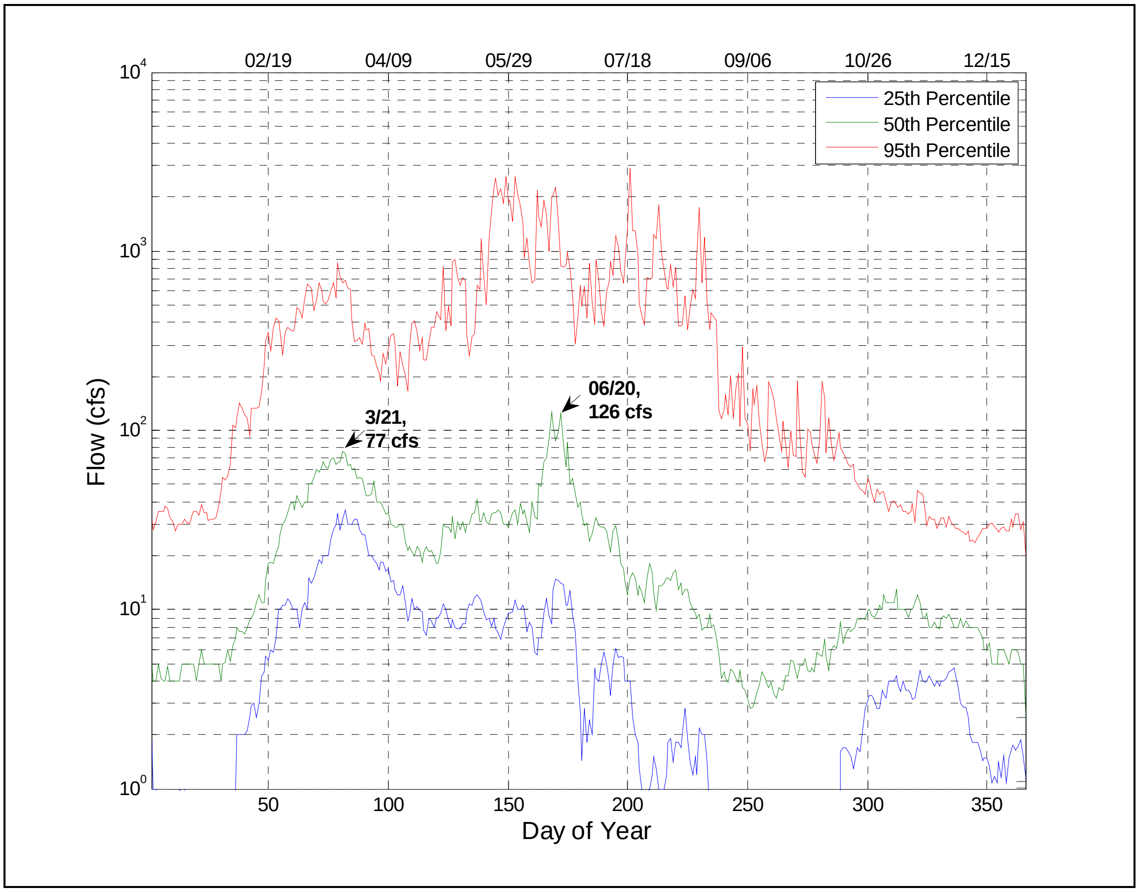

Figure 5.3-3 Annual Hydrograph for USGS Gage 06395000 on the Cheyenne River at Edgemont, SD from 1903 to 2008

5.3.2 Beaver Creek Basin

The Beaver Creek Basin is 1360 mi2, excluding the Pass Creek sub-basin. It extends from a few miles northwest of Upton, WY to about eight miles southeast of Dewey, SD and lies within Weston, Niobrara and Crook Counties in Wyoming, and within Pennington, Custer and Fall River Counties in South Dakota. Beaver Creek is a perennial stream with ephemeral tributaries. Discharge data for Beaver Creek is collected at USGS gage 06394000 near Newcastle, WY (Figure 5.3-1). Figure 5.3-4 shows an annual hydrograph with the 25th, 50th and 95th flow percentiles for this gage from 1944 to 1998. Figure 5.3-5 shows monthly average flow data for this gage from 1944 to 1998.

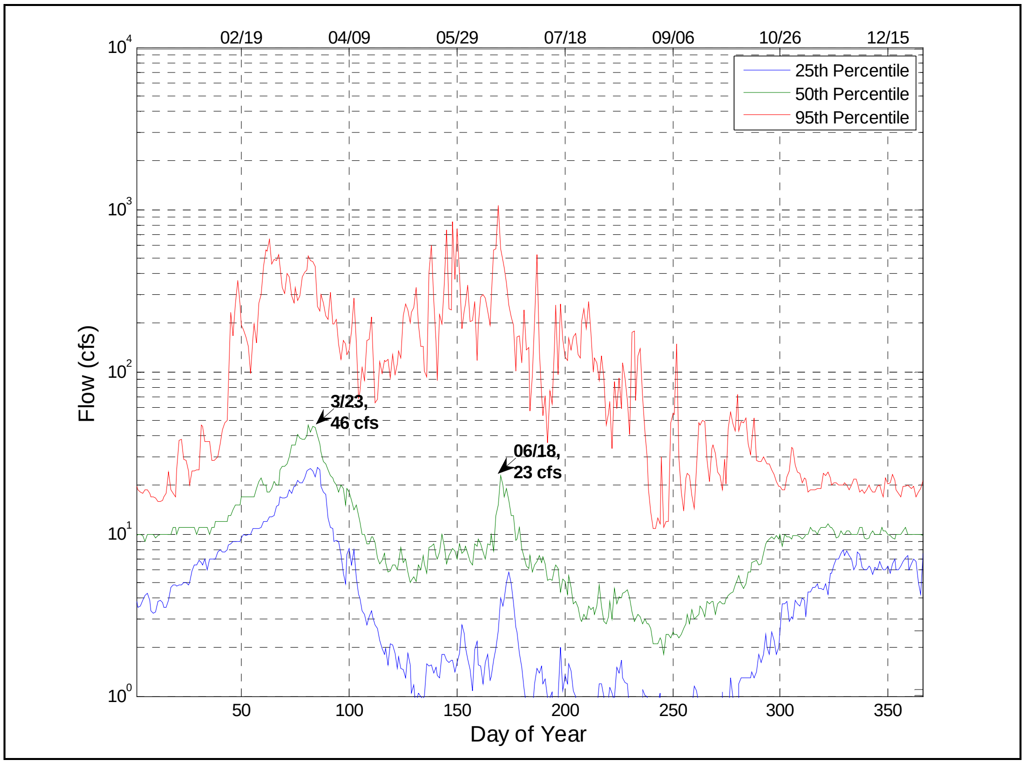

Figure 5.3-4 Annual Hydrograph for USGS Gage 06394000 on Beaver Creek near Newcastle, WY from 1944 to 1998

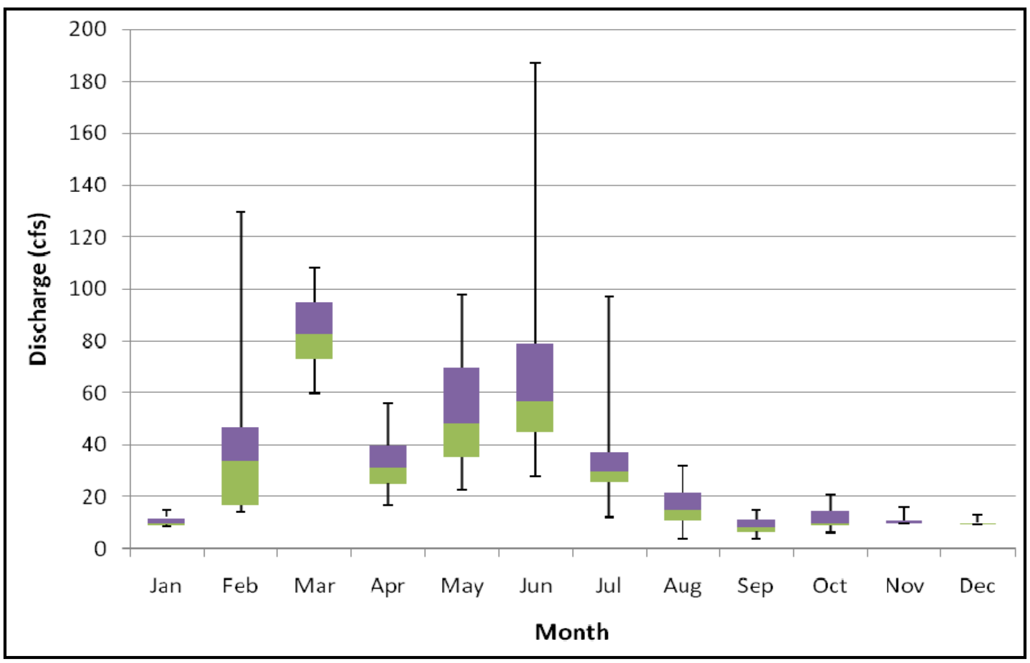

Figure 5.3-5 Monthly average flows at USGS gage 06394000 on Beaver Creek near Newcastle, WY from 1944 to 1998

5.3.3 Pass Creek Watershed

The Pass Creek watershed, characterized as a subbasin of the larger Beaver Creek Basin, comprises most of the east-southeast portion of the Beaver Creek Basin and is almost fully contained in South Dakota. The Pass Creek watershed is 230 mi^2 and is located in Custer, Fall River, and Pennington Counties in South Dakota and a very small portion of Weston County in Wyoming. Pass Creek is dry except for brief periods of runoff following major storms. There is no permanent stream flow gage stationed along Pass Creek.

5.3.4 Surface Water Quality

The proposed PAA is drained by the Cheyenne River and its tributaries (Figure 5.3-1). Beaver Creek and Pass Creek drain the proposed permit area and discharges into the Cheyenne River downstream of the proposed permit area. Beaver Creek drains the southeastern portion of Weston County in Wyoming before entering Custer County in South Dakota and discharging to the Cheyenne River south of Burdock in Fall River County. Beaver Creek drains approximately 1670 mi^2 (1,069,000 acres); 71 percent of the watershed is in Wyoming and 29 percent is in South Dakota. The Pass Creek watershed, characterized as a sub basin of the larger Beaver Creek basin, comprises most of the east-southeast portion of the Beaver Creek basin and is almost fully contained in South Dakota. The Pass Creek watershed is 230 mi^2 and is located in Custer, Fall River, and Pennington Counties in South Dakota and a very small portion of Weston County in Wyoming. Several smaller ephemeral tributaries are also located within or adjacent to the proposed permit area. These streams, including the Cheyenne River, often experience extended periods of no flow. Water quality varies considerably and is dependent on the flow regime. Relatively high amounts of sediment and low dissolved solids occur during periods of high flows, while less turbid waters with higher dissolved solids occur during periods of low flows (Krantz, 2006).

All surface waters in the State of South Dakota are classified into one or more of the following beneficial uses:

1. Domestic water supply waters
2. Coldwater permanent fish life propagation waters
3. Coldwater marginal fish life propagation waters
4. Warm water permanent fish life propagation waters
5. Warm water semi-permanent fish life propagation waters
6. Warm water marginal fish life propagation waters
7. Immersion recreation waters
8. Limited contact recreation waters
9. Fish and wildlife propagation, recreation, and stock watering waters
10. Irrigation waters
11. Commerce and industry waters

Table 5.3-1 gives State of South Dakota assigned beneficial uses for Beaver Creek, Cheyenne River, and Pass Creek. Water quality standards associated with beneficial uses of Cheyenne River, Beaver Creek, and Pass Creek are given in Table 5.3-2.

Table 5.3-1 Beneficial uses of Streams in and near the Dewey-Burdock Permit Area

Water body	Uses
Beaver Creek	3, 8, 9, 10
Cheyenne River (from Wyoming border to Angostura Reservoir)	5, 8, 9, 10
Pass Creek	9, 10

Table 5.3-2 Beneficial Use Numeric Criteria

Oil and Grease				≤ 10.0	

[1] Thirty-day average
[2] Daily maximum
[3] Calculation based on temperature and pH

Cheyenne River in South Dakota upstream and downstream of the proposed permit boundary is classified as having beneficial uses 5, 8, 9, and 10. According to the State of South Dakota 2006 303(d) list, the Cheyenne River from the Wyoming border to Beaver Creek is impaired with respect to beneficial uses fish and wildlife propagation, recreation, and stock watering (9), and irrigation (10) due to high levels of total dissolved solids (TDS), sodium adsorption ratio (SAR), and conductivity. The rivers support status related to warm water semi-permanent fish life propagation (5) and limited contact recreation (8) is listed as "insufficient info" (SD DENR, 2006). The Cheyenne River from Beaver Creek to Angostura Reservoir is listed as supporting the beneficial use of limited contact recreation (8), but is impaired for the other three uses (5, 9, 10) due to high levels of TDS, SAR, conductivity, and total suspended solids (TSS).

Beaver Creek in South Dakota has been classified as being suitable for the same uses as the Cheyenne River except that this stream has been classified as being suitable for cold water marginal fish life propagation rather than warm water semi-permanent fish life propagation. The State of Wyoming has classified Beaver Creek in the PAA vicinity as presently supporting game fish or having the potential to support game fish. Beaver Creek has also been classified by Wyoming as a warm water fishery. Beaver Creek is listed as impaired from the Wyoming border to the confluence with the Cheyenne River with respect to all assigned beneficial uses due to high conductivity, TDS, TSS, fecal coliform, SAR, and temperature.

Pass Creek is classified by the State of South Dakota as having the beneficial uses of fish and wildlife propagation, recreation, and stock watering (9), and irrigation (10). Pass Creek is listed as being in full support of assigned beneficial uses.

Surface Water Management

All of the Dewey-Burdock facilities are located outside of the FEMA 100-year flood plain. For well fields and non-CPP/SF areas, stormwater management will include general grading of roads and building pads to promote positive drainage toward existing water courses. Best management practices (BMPs) for sediment control during construction and operations will be provided until vegetative cover on disturbed ground has been restored. Such practices will include, but not be limited to, use of silt fences and hay bales downstream of disturbed areas, and as necessary, long-term erosion protection using stream channel armoring such as rip rap, gabions, and/or geotextiles.

For the CPP site area, SF site, and contiguous impervious services, excess runoff above pre-existing conditions will be temporarily detained to assure that peak runoff flow following construction does not exceed peak runoff flow prior to construction. BMPs will include construction of bermed parking lots with controlled outlet structures, routing flow into stormwater detention ponds with controlled outlet structures, or some combination thereof. In addition, sediment control during construction will be accomplished using similar BMPs.

Surface water/groundwater interactions and potential impacts to these media from site activities are discussed in Section 7.8.1.9 and 7.9.9 of this application.

5.4 Ecological Resources

5.4.1 Introduction

This section provides a general discussion of the affected environment and environmental consequences to vegetative resources, vertebrate terrestrial wildlife, and aquatic species (vertebrates and macro-invertebrates). The subsequent sub-sections address the potential impacts to vegetative communities and specific groups of wildlife species (hereafter, includes both terrestrial and aquatic species unless specified). As no underground or open pit mining would occur as part of the Proposed Action, the impact analysis in this document is limited to the Proposed Action (ISL of uranium resources) and No Action alternatives.

Ecological baseline studies for flora and fauna were collected to fulfill the objectives specified in U.S. Nuclear Regulatory Commission (NRC) NUREG-1748, *Environmental Review Guidance for Licensing Actions Associated with NMSS Programs*. Ecological surveys were also conducted in accordance with applicable SD DENR, SDGFP, and U.S. Fish and Wildlife Service (USFWS) guidelines. These agencies were consulted prior to initiating field surveys to ensure that adequate objectives, survey methodologies, and data collection techniques were employed.

5.4.2 Regional Setting

The PAA (license area) spans approximately 10,580 acres in Townships (T) 6-7 South (S), Range (R) 1 East (E). Approximately 2,488 acres (23 percent) are expected to be disturbed by ISL operations associated with this project. The PAA is comprised primarily of private lands small portions of BLM lands and lies adjacent to parcels of USFS land. The current principal land use in the region is cattle grazing.

The PAA is within the mixed grass eco-region of the Northern Great Plains (EPA 1993), near the southwestern extension of the Black Hills. The elevation within the PAA ranges from approximately 3,600 feet to 3,900 feet above mean sea level, with the highest elevations along the pine breaks that overlap its eastern boundary. Topography in the PAA and surrounding lands is primarily gently rolling in the western quarter, with more varied terrain in the pine breaks and dissected hills that comprise the rest of the area.

The PAA is comprised of five main vegetative communities, in descending order: Ponderosa Pine Woodland, Big Sagebrush Shrubland, Greasewood Shrubland, Upland Grassland, and Cottonwood Gallery. Despite the overall ranking, Upland Grassland was present in the largest individual parcels. Interspersed among those primary habitats are smaller inclusions of Silver Sagebrush Shrubland, Agricultural Land, creek channels, and numerous ephemeral draws.

The overall PAA (license area and surrounding perimeter) is located within the Cheyenne River watershed. Two main stream channels pass through the PAA: Beaver Creek (perennial) and Pass Creek (intermittent). Both flow south into the Cheyenne River, which runs from west to east approximately 2.5 miles south of the PAA boundary. A few small stock reservoirs are scattered throughout the area, though they may not retain water year-round.

Trees are present along the riparian corridors of both primary creeks, and on the higher elevation hilltops in the PAA. The plains cottonwood (*Populus deltoides*) was the only tree present along the creek channels, and was more prevalent in the Pass Creek corridor. Ponderosa pine (*Pinus ponderosa*) dominates the higher elevation hilltops and breaks in the central and eastern portions of the PAA, with Rocky Mountain juniper (*Juniperus scopulorum*) present as individual trees or small inclusions in some of the dry drainages.

The PAA is characterized as semi-arid continental or steppe with a dry winter season. The area commonly experiences low precipitation levels, high evaporation rates, low relative humidity, and plentiful sunshine. Temperatures are moderate, with large diurnal and annual variations, and extremes ranging from approximately -37 degrees Fahrenheit (°F) in the winter to 114 °F in the summer. The first freeze typically occurs in mid- to late September, with the last freeze often recorded during late May.

Yearly precipitation totals average about 14 inches. Approximately one-half of the annual precipitation falls during the months of May, June, and July. As expected, most of the winter precipitation occurs as snow, with an annual average of 37 inches. Thunderstorms are relatively frequent in the PAA during the summer months, averaging 40-45 days per year. Much of the annual rainfall is associated with these events.

Powertech (USA) Inc.

Windy conditions are fairly common in the PAA and generally average about 10 miles per hour (mph). Prevailing winds come from the west-northwest during much of the year, though east-southeast winds are also common.

5.4.2.1 Climate General

The PAA is characterized as semi-arid continental or steppe with a dry winter season. The area commonly experiences low precipitation levels, high evaporation rates, low relative humidity, and plentiful sunshine. Temperatures are moderate, with large diurnal and annual variations, and extremes ranging from approximately -37 degrees F in the winter to 114 degrees F in the summer. The first freeze typically occurs in mid- to late September, with the last freeze often recorded during late May.

Yearly precipitation totals average about 14 inches. Approximately one-half of the annual precipitation falls during the months of May, June, and July. As expected, most of the winter precipitation occurs as snow, with an annual average of 37 inches. Thunderstorms are relatively frequent in the PAA during the summer months, averaging 40-45 days per year. Much of the annual rainfall is associated with these events.

Windy conditions are fairly common in the PAA, generally averaging 10 mph. Prevailing winds come from the west-northwest during much of the year, though east-southeast winds are also common.

5.4.3 Baseline Data

Ecological baseline studies for flora and fauna were collected to fulfill the objectives specified in U.S. NRC NUREG-1569, *Standard Review Plan for ISL Leach Uranium Extraction License Applications*. Ecological surveys were also conducted in accordance with applicable SD DENR, SDGFP, and USFWS established guidelines. These agencies were consulted prior to initiating field surveys to ensure that adequate objectives, survey methodologies, and data collection techniques were employed.

Vegetation sampling was conducted by BKS Environmental Associates, Inc. (BKS) of Gillette, Wyoming. Initial surveys were conducted during July 2007, with supplemental sampling performed to adjust to subsequent changes in the PAA boundary. Wildlife and aquatics sampling were conducted by ICF Jones & Stokes (formerly Thunderbird-Jones & Stokes), of Gillette, Wyoming from July 2007 through early August 2008 to meet agency requirements of one year of baseline data, and to accommodate changes to the PAA boundary during that period.

The following sections were generated from the final survey reports completed by BKS and Jones & Stokes for this project.

5.4.4 Terrestrial Ecology

Powertech (USA) conducted terrestrial ecological baseline field surveys including vegetation, wetlands, wildlife. The methodology and results are discussed in the following sections.

5.4.4.1 Vegetation

5.4.4.1.1 Survey Methodology

General

All sampling procedures and methodologies are consistent with standard industry practices utilized in applications for AEA licenses including those for: Smith Ranch, Nichols Ranch, Moore Ranch and Highlands Ranch. Refer to Appendix 5.4-A for the submitted methodology.

POWERTECH (USA) INC.

Mapping
Seven different plant communities were identified for the PAA, i.e., Big Sagebrush Shrubland (BS), Greasewood Shrubland (GW), Ponderosa Pine Woodland (PP), Upland Grassland (UG), Cottonwood Gallery (CG), Silver Sagebrush Shrubland (SS), and Agricultural Land (AG), using 2001 color infra-red (CIR) aerial photography, which was verified by field survey. The Agricultural Land was not sampled as it was actively being used for crop production. The Silver Sagebrush Shrubland will be described as an inclusion of the Greasewood Shrubland Community.

Transect Origin Selection
Transects were randomly located in the field within each sampled vegetation community. Each transect was at least 150 feet from the previous transect. Random numbers between 1 and 360 were generated to determine cover transect direction, and compasses were utilized to orient transects to the nearest 1/8 of 360 degrees in the field. Each sample site was marked with hand-held Garmin Global Positioning System (GPS), and these points were later plotted on the final vegetation survey map (Exhibit 5.4-1).

Cover
A sample size of 37 50-m point-intercept cover transects were sampled within the Ponderosa Pine Woodland and Greasewood Shrubland communities, while 27 samples were taken in the Big Sagebrush Shrubland, 26 samples for the Cottonwood Gallery and 30 samples for the Upland Grassland community for a total of 157 cover points in the PAA.

In the vegetation communities, each 50-m transect represented a single sample point. Percent cover measurements were taken from point-intercepts at 1-m intervals along a 50-m transect. Transects that exceeded the boundaries of the vegetation community being sampled were redirected back into its vegetation community at a 90 degree angle from the original transect direction at the point of intercept. In instances where a 90 degree angle of reflection did not place the transect within the sampled community, a 45 degree angle of reflection was used. Each point-intercept represents 2 percent towards cover measurements.

Percent cover measurements record “first-hit” point-intercepts by live foliar vegetation species, litter, rock, or bare ground. Multiple hits on vegetation were recorded, but used only for the purpose of constructing a plant species list for each plant community (Appendix 5.4-B).

Total Vegetation Cover
Vegetation data cover was recorded by species, using first hit data. All point intercepts of living vegetation and growth produced during the current growing season was counted toward total vegetation cover. Total vegetation cover measurements were expressed in absolute percentages for each sample point. Percent vegetation cover is the vertical projection of the general outline of plants to the ground surface. Cover summaries for each vegetation community are contained in Appendix 5.4-C.

Total Ground Cover
Total ground cover data was recorded by live vegetation, litter, or rock, minus bare ground. Litter includes all organic material that is dead including manure. Rock fragments were recorded when equal to or greater than two cm in size (i.e., sheet flow, minimum non-erodible particle size). Total ground cover measurements were expressed in absolute percentages for each sample point. Total ground cover equals the sum of cover values for percent vegetation, percent litter, and percent rock.

Shrub Density
This data was taken at the time of cover sampling to ensure adequate use of field time. Summarization of that data can be found in Appendix 5.4-C.

Shrub density data was collected in conjunction with randomly selected cover transects, wherever possible. All shrubs, full, half, or sub, were counted within 50 cm on either side of the 50-m cover transect (1 m x 50 m belt transect), yielding a 100 square meters (m^2) belt transect. Sample adequacy was not calculated for shrub density. The number of belt transects equaled the number of cover transects for a given vegetation type.

Tree Density
This data was taken at the time of cover sampling to ensure adequate use of field time. Summarization of that data can be found in Appendix 5.4-D..

Tree density data was collected in the Ponderosa Pine Woodland vegetation community in conjunction with randomly selected cover transects, wherever possible. Tree density in this community was determined using the point-center quarter method. Trees within the Cottonwood Gallery or Riparian areas were directly counted on an aerial photograph. Within other vegetation communities, individual *Pinus ponderosa* (Ponderosa Pine) or other tree species found were directly counted for numbers. Sample adequacy was not calculated on the point-center quarter plots.

Species Composition
A list of plant species encountered during 2007 quantitative sampling is compiled in Appendix 5.4-B by vegetation community type for each of the five vegetation communities. The species list includes plant species sampled in cover transects as well as plant species observed along the belt transect. Plant names in the Rocky Mountain Vascular Plants of Wyoming (Dorn 2001, 3rd Edition) were utilized. Plant identification was confirmed by Robert Dorn, when necessary. Scientific nomenclature followed that in use at the Rocky Mountain Herbarium in Laramie, Wyoming, during 2007.

Sample Adequacy
A minimum of 20 cover transects per vegetation type was sampled in five vegetation communities. Sample adequacy was calculated and an incremental number of cover transects was sampled up the maximum of 50.

The following sample adequacy formula was utilized to determine the minimum required size of the sample population.

$$n_{min} \geq \frac{2(sz)^2}{(dx)^2}$$

Where n_{min}= minimum number of sampled line transects needed to adequately represent native vegetation types

s= sample standard deviation
z= the z statistic
d= the amount of reduction desired
x= sample mean for cover

This sample adequacy formula is used by the WDEQ. The 2 in the numerator makes this a very conservative test. The term "grassland" indicates that a community has less than or equal to 20 percent relative cover by shrub species while a "shrubland" is greater than or equal to 20 percent relative cover by shrub species according to the WDEQ.

The five vegetation communities have been identified as “grassland”, or “shrubland”. Upland Grassland is identified as grassland while the Ponderosa Pine Woodland, Big Sagebrush Shrubland, Greasewood Shrubland, and Cottonwood Gallery communities are identified as shrublands. The constant values to be used in statistical tests for cover are: “z”=1.28 and “d” = 0.1 for grasslands and shrublands. All sampled vegetation was included in the sample adequacy test (i.e., “undesirable” species were not eliminated from the equation). Also as adjustments were made to the permit boundary, the samples that fell outside of the boundary were not excluded as they were initially part of the boundary at the time of survey.

Extended Reference Area
The Extended Reference Area (EXREFA) is a native land unit used to evaluate revegetation success on portions of the same native plant community that could be affected by the Proposed Action. This study shows the Proposed Action will affect five plant communities, Big Sagebrush Shrubland, Cottonwood Gallery, Greasewood Shrubland, Ponderosa Pine Woodland, and Upland Grassland. All areas of these communities not affected by the Proposed Action may serve as the EXREFA.

5.4.4.1.2 Vegetation Survey Results

Mapping
Approximately 10,557 acres of the PAA was surveyed. Of these acres, Big Sagebrush Shrubland was 2,501.74 acres (23.70 percent), Greasewood Shrubland was 2,190.45 acres (20.75 percent), Ponderosa Pine Woodland was 2,183.76 acres (20.69 percent), Upland Grassland was 2,187.56 acres (20.72 percent), Agricultural Land was 780.79 acres (7.40 percent), Disturbed areas were 14.7 acres (0.14 percent), existing mine pits were 326.99 acres (3.10 percent), Cottonwood Gallery was 240.6 acres (2.28 percent), Silver Sagebrush Shrubland was 119.49 acres (1.13 percent), water was 8.94 acres (0.08 percent), and Shale Outcrop was 2.19 acres (0.02 percent). Refer to Table 5.4-1 for acreage of each vegetation community by permit acreage, and ½-mile buffer acreage.

Table 5.4-1 Acreage and Percent of Total Area for Each of the Map Units

Map Unit	Permit area	% of Area	1/2 Mile Buffer Area	% of Area
Sampled Vegetation Communities				
Big Sagebrush Shrubland	2,501.56	23.70	2,639.45	31.75
Greasewood Shrubland	2,190.45	20.75	837.66	10.07
Ponderosa Pine Woodland	2,183.76	20.69	2,036.58	24.49
Upland Grassland	2,187.56	20.72	2,027.18	24.38
Cottonwood Gallery	240.6	2.28	103.13	1.24
Described Vegetation Communities				
Agricultural Land	780.79	7.40	604.19	7.27
Disturbed	14.7	0.14	--	--
Existing Mine Permit	326.99	3.10	--	--
Silver Sagebrush Shrubland	119.49	1.13	53.65	0.65
Shale Outcrop	2.19	0.02	--	--
Water	8.94	0.08	12.6	0.15
TOTAL	**10,557.03**	**100.00**	**8,314.44**	**100.00**

General
The EXREFA will remain unaffected over the course of the proposed the Proposed Action and will be used to evaluate revegetation success. The EXREFA will include portions of the same native plant communities that area affected by the Proposed Action but located outside those disturbed areas and within PAA.

5.4.4.1.3 Big Sagebrush Shrubland

Cover
The Big Sagebrush Shrubland community comprised 2,501.56 of the 10,557.03 acres of the PAA (23.70 percent). Twenty-seven cover transects were sampled for this community. Absolute total vegetation cover was 45.89 percent. Absolute bare soil and litter/rock percentages were 14.07 percent and 38.52 percent, respectively. Absolute total ground cover was 85.78 percent. *Bouteloua gracilis* (blue grama), provided the highest relative vegetation cover at 24.38 percent, while *Buchloe dactyloides* (buffalograss) provided the next highest relative vegetation cover at 20.98 percent. Refer to Table 5.4-2 for the absolute cover values.

Table 5.4-2 2007 Absolute Cover for the Big Sagebrush Shrubland Vegetation Community

Vegetation Parameter
Absolute Total Vegetation Cover (45.89%)
Absolute Total Cover (85.78%)

Sample Adequacy
There were 27 samples taken in the Big Sagebrush Shrubland plant community. The sample adequacy formula outlined earlier was utilized to determine the minimum required size of the sample population. Big Sagebrush Shrubland met sample adequacy
Refer to Table 5.4-3 below for sample adequacy values.

Table 5.4-3 Summary of Sample Adequacy Calculations for Percent Vegetation Cover in the Big Sagebrush Shrubland

Map Unit	Mean	Standard Deviation	Sample Adequacy	Actual Sample #	Z-Value	Confidence Level Achieved
Big Sagebrush Shrubland						
Total Vegetation Cover	22.75	6.52	26.91	27.00	2.56	99.48
Total Ground Cover	42.64	3.49	2.20	27.00	8.98	NA

Shrub Density
Big Sagebrush Shrubland supported an average of 3,661.46 shrubs per acre or 0.90 shrubs/m^2. The following full and half/sub-shrub species were found: *Artemisia tridentata* (big sagebrush), *Artemisia frigida* (fringed sagewort), and *Gutierrezia sarothrae* (broom snakeweed). Refer to Appendix 5.4-D for a complete Big Sagebrush Shrubland density summary.

Species Composition
Species composition for the Big Sagebrush Shrubland community was dominated by warm season perennial grasses with 46.33 percent relative vegetation cover, followed by cool season perennial grasses with 20.33 percent relative vegetation cover. Perennial shrubs had 15.82 percent relative vegetation cover, while annual grasses had 10.15 percent relative vegetation cover. Annual forbs had 1.90 percent relative vegetation cover. Perennial forbs had 1.11 percent relative vegetation cover; sub-shrubs had a total of 2.59 percent relative vegetation cover. Succulents had 1.77 percent relative vegetation cover. The cool season perennial grasses were mainly *Elymus smithii* (western wheatgrass), *Carex filifolia* (threadleaf sedge), and *Poa secunda* (Sandberg bluegrass). The warm season perennial grasses were mainly blue grama, buffalograss, and *Bouteloua curtipendula* (sideoats grama). Annual grasses were *Bromus japonicus* (Japanese brome) and *Bromus tectorum* (cheatgrass). Perennial forbs were dominated by *Calochortus nuttallii* (sego lily), *Phlox spp.* (phlox), and *Sphaeralcea coccinea* (scarlet globemallow). Annual forbs included *Alyssum desertorum* (desert alyssum) and *Lepidium densiflorum* (prairie peppergrass). Present shrubs/sub-shrubs was big sagebrush, fringed sagewort, and broom snakeweed. Also present was the succulent *Opuntia polyacantha* (plains prickly pear). Refer to Table 5.4-4 for relative Big Sagebrush Shrubland cover summary and Appendix 5.4-C for a complete Big Sagebrush Shrubland cover summary.

Table 5.4-4 Vegetation Cover Sampling Data Summary of Species by Lifeform for the Big Sagebrush Shrubland Community

	Vegetation Cover	
	Absolute	Relative (%)
Cool Season Perennial Grasses	9.33	20.33
Warm Season Perennial Grasses	21.26	46.33
Annual Grasses	4.66	10.15
Annual Forbs	0.87	1.90
Perennial Forbs	0.51	1.11
Perennial Shrubs	7.26	15.82
Perennial Sub-Shrubs	1.19	2.59
Succulents	0.81	1.77

5.4.4.1.4 Greasewood Shrubland

Cover

The Greasewood Shrubland community comprised 2,190.45 of the 10,557.03 acres of the PAA (20.75 percent). Thirty-seven cover transects were sampled for this community. Absolute total vegetation cover was 37.11 percent. Absolute bare soil and litter/rock percentages were 18.70 percent and 42.54 percent, respectively. Absolute total ground cover was 81.41 percent. Western wheatgrass provided the highest relative vegetation cover at 23.31 percent. *Sarcobatus vermiculatus* (greasewood), provided the next highest cover at 22.88 percent. Refer to Table 5.4-5 for the absolute cover values.

Table 5.4-5 2007 Absolute Cover for the Greasewood Shrubland Vegetation Community

Vegetation Parameter	Mean
Absolute Vegetation Cover (%)	37.11
Absolute Total Cover (%)	81.41

Sample Adequacy

There were 37 samples taken in the Greasewood Shrubland community. The sample adequacy formula outlined earlier was utilized to determine the minimum required size of the sample population. Greasewood Shrubland met sample adequacy. Refer to Table 5.4-6 for sample adequacy values.

Table 5.4-6 Summary of Sample Adequacy Calculations for Percent Vegetation Cover in the Greasewood Shrubland

Map Unit	Mean	Standard Deviation	Sample Adequacy	Actual Sample #	Z-Value	Confidence Level Achieved
Greasewood Shrubland						
Total Vegetation Cover	18.84	5.80	31.06	37.00	2.79	99.74
Total Ground Cover	40.70	6.74	8.99	37.00	5.19	NA

Shrub Density

Greasewood Shrubland supported an average of 2,589.42 shrubs per acre or 0.64 shrubs/m^2. The following full and half/sub-shrub species were found: greasewood, big sagebrush and *Artemisia cana* (silver sagebrush), *Ericameria nauseosa* (rubber rabbitbrush), and fringed sagewort. Refer to Appendix 5.4-D for a complete Greasewood Shrubland density summary

Species Composition

Species composition for the Greasewood Shrubland community was dominated by perennial shrubs with 28.70 percent relative vegetation cover, followed by cool season perennial grasses with 27.67 percent relative vegetation cover. Warm season perennial grasses had 24.31 percent relative vegetation cover. Annual grasses had 4.96 percent relative vegetation cover while annual forbs had 10.32 percent relative vegetation cover. Perennial forbs had 0.40 percent relative vegetation cover. Succulents had 3.64 percent relative vegetation cover. The cool season perennial grasses were mainly western wheatgrass, *Agropyron cristatum* (crested wheatgrass), threadleaf sedge, *Bromus inermis* (smooth brome), and *Elymus lanceolatus* (thickspike wheatgrass). Warm season perennial grasses were mainly blue grama, buffalograss, *Distichlis stricta* (inland saltgrass), and *Sporobolus airoides* (alkali sacaton). Annual grasses were dominated by Japanese brome and cheatgrass. Perennial forbs were dominated by scarlet globemallow, *Ambrosia psilostachya* (western ragweed), and *Convolvulus arvensis* (field bindweed). Annual forbs included *Bassia sieversiana* (summer cypress), *Plantago patagonica* (Pursh's plantain), and *Monolepis nuttalliana* (Nuttall's povertyweed). Shrubs included greasewood, big sagebrush and silver sagebrush. Plains prickly pear was also present. An area dominated by silver sagebrush was present within this community. This area was wetter than the typical greasewood community. The species composition was likely similar except for the dominance of silver sagebrush in the shrub component which is due to the increased moisture present within this area. Refer to Table 5.4-7 for relative Greasewood Shrubland cover summary and Appendix 5.4-C for a complete Greasewood Shrubland cover summary.

Table 5.4-7 Vegetation Cover Sampling Data Summary of Species by Lifeform for the Greasewood Shrubland Community

	Vegetation Cover	
	Absolute	**Relative (%)**
Cool Season Perennial Grasses	10.27	27.67
Warm Season Perennial Grasses	9.02	24.31
Annual Grasses	1.84	4.96

Perennial Forbs	0.15	0.40
Perennial Shrubs	10.65	28.70
Succulents	1.35	3.64

5.4.4.1.5 Ponderosa Pine Woodland

Cover

The Ponderosa Pine Woodland community comprised approximately 2,188.76 of the 10,557.03 acres of the PAA (20.69 percent). Thirty-seven cover transects were sampled for this community. Absolute total vegetation cover was 34.33 percent. Absolute bare soil and litter/rock percentages were 10.54 and 53.57, respectively. Absolute total ground cover was 88.92 percent. *Pinus ponderosa* (ponderosa pine) provided the highest relative vegetation cover at 45.03 percent, while *Carex geyeri* (Geyer's sedge) provided the next highest relative vegetation cover at 13.37 percent. Refer to Table 5.4-8 for the absolute cover values.

Table 5.4-8 2007 Absolute Cover for the Ponderosa Pine Woodland Vegetation Community

Vegetation Parameter	Mean
Absolute Total Vegetation Cover (%)	34.33
Absolute Total Cover (%)	88.92

Sample Adequacy
There were 37 samples taken in the Ponderosa Pine Woodland community. The sample adequacy formula outlined earlier was utilized to determine the minimum required size of the sample population. Ponderosa Pine Woodland met sample adequacy. Refer to Table 5.4-9 below for sample adequacy values.

Table 5.4-9 Summary of Sample Adequacy Calculations for Percent Vegetation Cover in the Ponderosa Pine Woodland

Map Unit	Mean	Standard Deviation	Sample Adequacy	Actual Sample #	Z-Value	Confidence Level Achieved
Ponderosa Pine Woodland						
Total Vegetation Cover	17.19	5.25	30.56	37.00	2.82	97.67
Total Ground Cover	44.19	3.86	2.50	37.00	3.80	NA

Shrub Density
Ponderosa Pine Woodland supported an average of 1,224.27 shrubs per acre or 0.30 shrubs/m^2. The following full and half/sub-shrub species were found: big sagebrush, silver sagebrush, rubber rabbitbrush, *Chrysothamnus viscidflorus* (Douglas rabbitbrush), fringed sagewort, broom snakeweed, *Rosa arkansana* (prairie rose), and *Yucca glauca* (yucca or small soapweed). Refer to Appendix 5.4-D for a complete Ponderosa Pine Woodland density summary.

Tree Density
Ponderosa Pine Woodland supported an average of 75.88 ponderosa pine trees per acre or 0.019 trees/m^2. *Juniperus scopulorum* (Rocky Mountain juniper) was also observed within this community; however no quantitative evaluations were made for this species. Refer to Appendix 5.4-E for a complete tree density summary for the Ponderosa Pine Woodland community.

Species Composition
Species composition for the Ponderosa Pine Woodland community was dominated by trees with 52.58 percent relative vegetation cover, followed by warm season perennial grasses with 22.34 percent relative vegetation cover. Cool season perennial grasses had 19.34 percent relative vegetation cover. Annual grasses had 0.79 percent relative vegetation cover while annual forbs had 0.44 percent relative vegetation cover. Biennial forbs had 0.15 percent relative vegetation cover, while perennial forbs had 1.22 percent relative vegetation cover. Succulents had 0.47 percent relative vegetation cover while perennial shrubs and sub-shrubs had 2.04 percent and 0.64 percent relative vegetation cover, respectively. The trees were dominated by ponderosa pine and *Juniperus scopulorum* (Rocky Mountain juniper). The cool season perennial grasses were mainly Geyer's sedge, western wheatgrass and *Hesperostipa comata* (needleandthread). Warm season perennial grasses were mainly blue grama, sideoats grama, *Schizachyrium scoparium* (little bluestem), and *Aristida purpurea var. fendleriana* (Fendler's threeawn). Annual grasses were dominated by Japanese brome and cheatgrass. Perennial forbs were dominated by *Erigeron spp.* (fleabane), *Thermopsis rhombifolia* (prairie thermopsis), *Antennaria parvifolia* (small-leaf pussytoes), *Liatris punctata* (dotted blazing star), and *Vicia americana* (American vetch). Annual forbs included *Chenopodium berlandieri* (pitseed goosefoot), *Draba nemorosa* (yellow draba), and *Lappula redowski* (beggars-tick). Biennial forbs included *Melilotus officinalis* (yellow sweetclover). The shrubs and subshrubs present were big sagebrush, silver sagebrush, and fringed sagewort. Plains prickly pear was also present. Refer to Table 5.4-10 for relative Ponderosa Pine Woodland cover summary and Appendix 5.4-C for a complete Ponderosa Pine Woodland cover summary.

Table 5.4-10 Vegetation Cover Sampling Data Summary of Species by Life form for the Ponderosa Pine Woodland Community

	Vegetation Cover	
	Absolute	Relative (%)
Cool Season Perennial Grasses	6.64	19.34
Warm Season Perennial Grasses	7.67	22.34
Annual Grasses	0.27	0.79
Annual Forbs	0.15	0.44
Biennial Forbs	0.05	0.15
Perennial Forbs	0.42	1.22

Perennial Sub-Shrubs	0.22	0.64
Succulents	0.16	0.47
Trees	18.05	52.58

5.4.4.1.6 Upland Grassland

Cover

The Upland Grassland community comprised approximately 2,187.56 of the 10,557.03 acres of the PAA (20.72 percent). Thirty cover transects were sampled for the Upland Grassland community. Originally there were 31 transects sampled in this community, however, upon review transect 26 was discarded due to the fact that it was not representative of the community. Absolute total vegetation cover was 46.02 percent. Absolute bare soil and litter/rock percentages were 11.07 and 41.13, respectively. Absolute total ground cover was 88.95 percent. Buffalograss provided the highest relative vegetation cover at 27.81 percent, while blue grama provided the next highest relative vegetation cover at 27.10 percent. Refer to Table 5.4-11 for the absolute cover values.

Table 5.4-11 Absolute Cover for the Upland Grassland Vegetation Community

Vegetation Parameter	Mean
Absolute Total Vegetation Cover (%)	46.02
Absolute Total Cover (%)	88.47

Sample Adequacy

There were 30 samples taken in the Upland Grassland community. The sample adequacy formula outlined earlier was utilized to determine the minimum required size of the sample population. Upland Grassland met sample adequacy. Refer to Table 5.4-12 for sample adequacy values.

Table 5.4-12 Summary of Sample Adequacy Calculations for Percent Vegetation Cover in the Upland Grassland

Map Unit	Mean	Standard Deviation	Sample Adequacy	Actual Sample #	Z-Value	Confidence Level Achieved
Upland Grassland						
Total Vegetation Cover	23.00	6.88	29.32	30.00	1.29	90.15
Total Ground Cover	44.23	3.04	1.55	30.00	5.63	NA

Shrub Density

Upland Grassland supported an average of 51.01 shrubs per acre or 0.01 shrubs/m^2. The following full and half/sub-shrub species were found: big sagebrush, fringed sagewort, and broom snakeweed. Refer to Appendix 5.4-D for a complete Upland Grassland density summary.

Species Composition

Species composition for the Upland Grassland community was dominated by warm season perennial grasses with 54.91 percent relative vegetation cover, followed by cool season perennial grasses with 27.66 percent relative vegetation cover. Annual grasses had 9.00 percent relative vegetation cover, while annual forbs had 3.35 percent relative vegetation cover. Perennial forbs had 0.43 percent relative vegetation cover. Subshrubs had a total 0.15 percent relative vegetation cover. Succulents had 4.50 percent relative vegetation cover. The cool season perennial grasses were dominated by western wheatgrass, threadleaf sedge, and crested wheatgrass. Warm season grasses were dominated by blue grama and buffalograss. Annual grasses were dominated by Japanese brome and cheatgrass. Perennial forbs included scarlet globemallow. Annual forbs included desert alyssum, prairie peppergrass, and *Thlaspi arvense* (field pennycress). Fringed sagewort was the only sub-shrub present. Also present was plains prickly pear. Refer Table 5.4-13 for relative Upland Grassland cover summary and to Appendix 5.4-C for an Upland Grassland complete cover summary.

Table 5.4-13 Vegetation Cover Sampling Data Summary of Species by Lifeform for the Upland Grassland Community

	Vegetation Cover	
	Absolute	**Relative (%)**
Cool Season Perennial Grasses	12.73	27.66
Warm Season Perennial Grasses	25.27	54.91
Annual Grasses	4.14	9.00
Annual Forbs	1.54	3.35
Perennial Forbs	0.20	0.43
Perennial Sub-Shrubs	0.07	0.15
Succulents	2.07	4.50

5.4.4.1.7 Cottonwood Gallery

Cover

The Cottonwood Gallery community comprised approximately 240.60 of the 10,557.03 acres of the PAA (2.28 percent). Twenty-six cover transects were sampled for the Cottonwood Gallery community. Absolute total vegetation cover was 62.61 percent. Absolute bare soil and litter/rock percentages were 1.19 and 17.50, respectively. Absolute total ground cover was 97.62 percent. Smooth brome provided the highest relative vegetation cover at 29.12 percent, while western wheatgrass provided the next highest relative vegetation cover at 26.29 percent. Refer to Table 5.4-14 for the absolute cover values.

Table 5.4-14 2007 Absolute Cover for the Cottonwood Gallery Vegetation Community

Vegetation Parameter	Mean
Absolute Total Vegetation Cover (%)	62.61
Absolute Total Cover (%)	97.62

Sample Adequacy

There were 26 samples taken in the Cottonwood Gallery community. The sample adequacy formula outlined earlier was utilized to determine the minimum required size of the sample population. Cottonwood Gallery met sample adequacy. Refer to Table 5.4-15 for sample adequacy values.

Table 5.4-15 Summary of Sample Adequacy Calculations for Percent Vegetation Cover in the Cottonwood Gallery

Map Unit	Mean	Standard Deviation	Sample Adequacy	Actual Sample #	Z-Value	Confidence Level Achieved
Cottonwood Gallery						
Total Vegetation Cover	31.31	7.65	19.56	26.00	2.95	99.84
Total Ground Cover	48.81	2.08	0.60	26.00	16.92	NA

Shrub Density
Cottonwood Gallery supported an average of 567.60 shrubs per acre or 0.14 shrubs/m^2. The following full and half/sub-shrub species were found: big sagebrush, silver sagebrush, rubber rabbitbrush, greasewood, and *Symphoricarpos occidentalis* (western snowberry). Refer to Appendix 5.4-D for a complete Cottonwood Gallery density summary.

Tree Density
Tree species within this community were counted on an aerial photograph. Upon counting the number of plains cottonwoods within the community was 295.

Species Composition
Species composition for the Cottonwood Gallery community was dominated by cool season perennial grasses with 55.41 percent relative cover, followed by trees with 21.37 percent relative cover. Warm season perennial grasses had 0.37 percent relative cover. Annual forbs had 18.06 percent relative cover while annual grasses had 1.23 percent relative cover. Perennial forbs had 2.33 percent relative cover. Shrubs had a total 1.23 percent relative cover. The cool season perennial grasses were dominated by smooth brome and western wheatgrass. The warm season perennial grasses included inland saltgrass. Annual grasses were dominated by Japanese brome and cheatgrass. Perennial forbs were dominated by *Cirsium arvense* (Canada thistle) and *Achillea millefolium* (common yarrow). Annual forbs included summer cypress and *Chenopodium album* (lambsquarters goosefoot). Present shrubs were silver sagebrush, greasewood, and *Symphoricarpos occidentalis* (western snowberry). *Populus deltoides* (plains cottonwood) was the only tree present. Refer to Table 5.4-16 below for relative Cottonwood Gallery cover summary and to Appendix 5.4-C for a Cottonwood Gallery complete cover summary.

Table 5.4-16 Vegetation Cover Sampling Data Summary of Species by Lifeform for the Cottonwood Gallery Community

	Vegetation Cover	
	Absolute	**Relative (%)**
Cool Season Perennial Grasses	34.69	55.41
Warm Season Perennial Grasses	0.23	0.37
Annual Grasses	0.77	1.23
Annual Forbs	11.31	18.06
Perennial Forbs	1.46	2.33
Perennial Shrubs	0.77	1.23
Trees	13.38	21.37

5.4.4.1.8 Vegetation Survey Discussion

The 10,580 acre PAA consists of five vegetation communities: Big Sagebrush Shrubland, Greasewood Shrubland, Ponderosa Pine Woodland, Upland Grassland, and Cottonwood Gallery. Each community was investigated for baseline vegetation information in support of a NRC Source Materials License and SD DENR Regular Mine Permit Application.

No threatened or endangered species were encountered within the PAA. The presence of the state designated weed Canada thistle was present within the Cottonwood Gallery vegetation community. The presence of the Fall River County designated weed field bindweed was present within the Greasewood Shrubland vegetation community.

5.4.4.2 Wetlands

5.4.4.2.1 Wetland Survey Methodology

The wetland surveys were conducted in accordance with the Interim Regional Supplement to the Corps of Engineers Wetland Delineation Manual: Great Plains Region. All WoUS and OWUS were assessed during the surveys. The routine wetland delineation approach with on-site inspection was utilized, and the survey was conducted by pedestrian reconnaissance and review of existing maps of the PAA. Identification of potential wetlands was based on visual assessment of vegetation and hydrology indicators, as well as intrusive soil sampling to determine the presence of wetland criteria indicators. Wetland Determination Data Forms-Great Plains Region-DRAFT, were utilized for each observation point. Hydrology and soils were evaluated whenever a plant community type met hydrophytic vegetation parameters based on the Dominance Test and Prevalence Index (as defined by the Great Plains Regional Supplement), or whenever indicators suggested the potential presence of a seasonal wetland area under normal circumstances.

Figure 5.4-1 below identifies Beaver Creek, Figure 5.4-2 identifies the Cottonwood Gallery, and Figure 5.4-3 identifies the concentration of old mine pits.

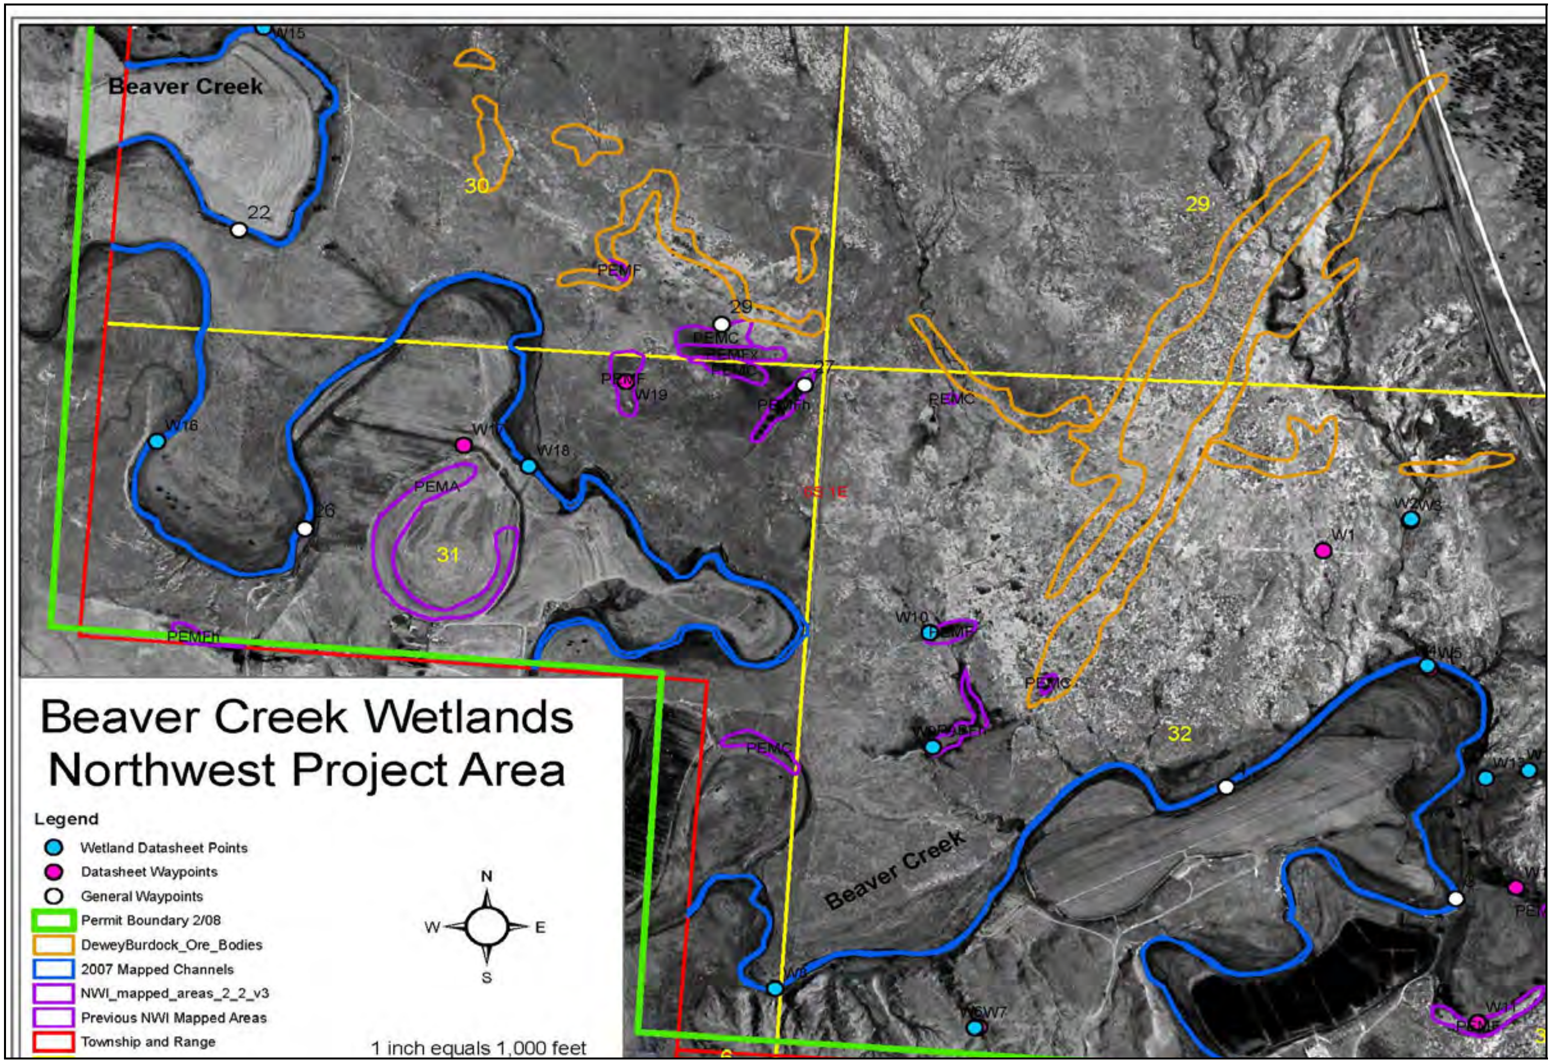

Figure 5.4-1 Beaver Creek Wetlands Northwest PAA

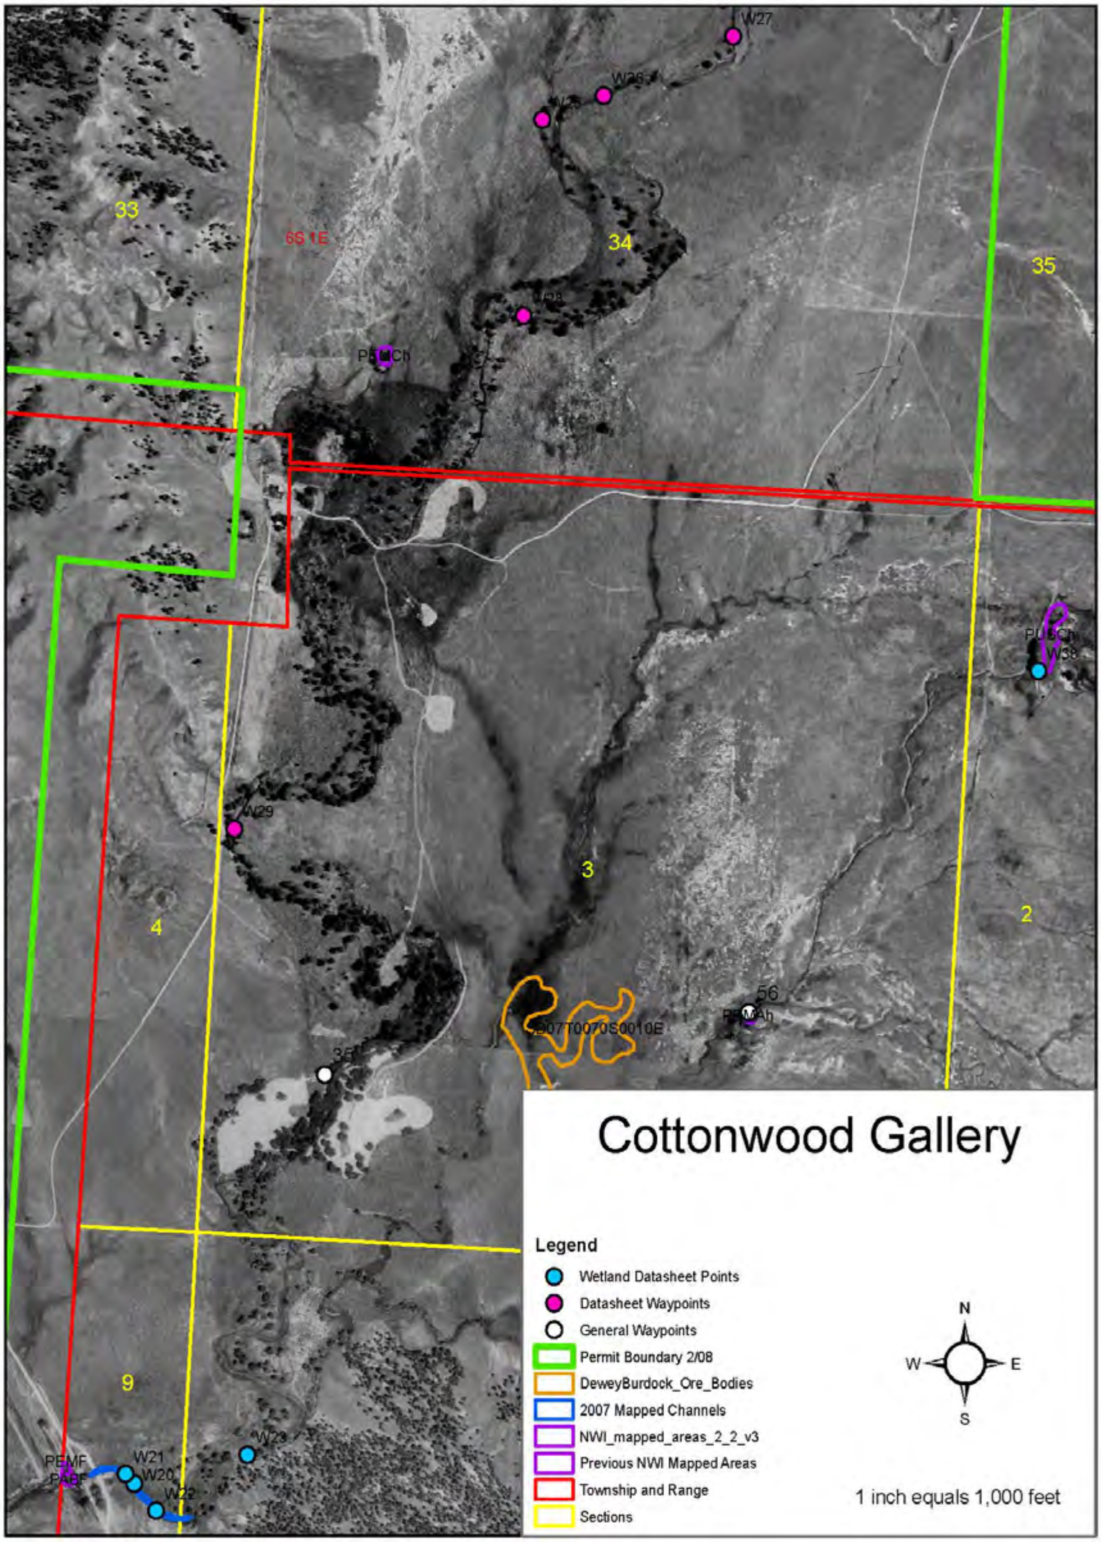

Figure 5.4-2 Cottonwood Gallery

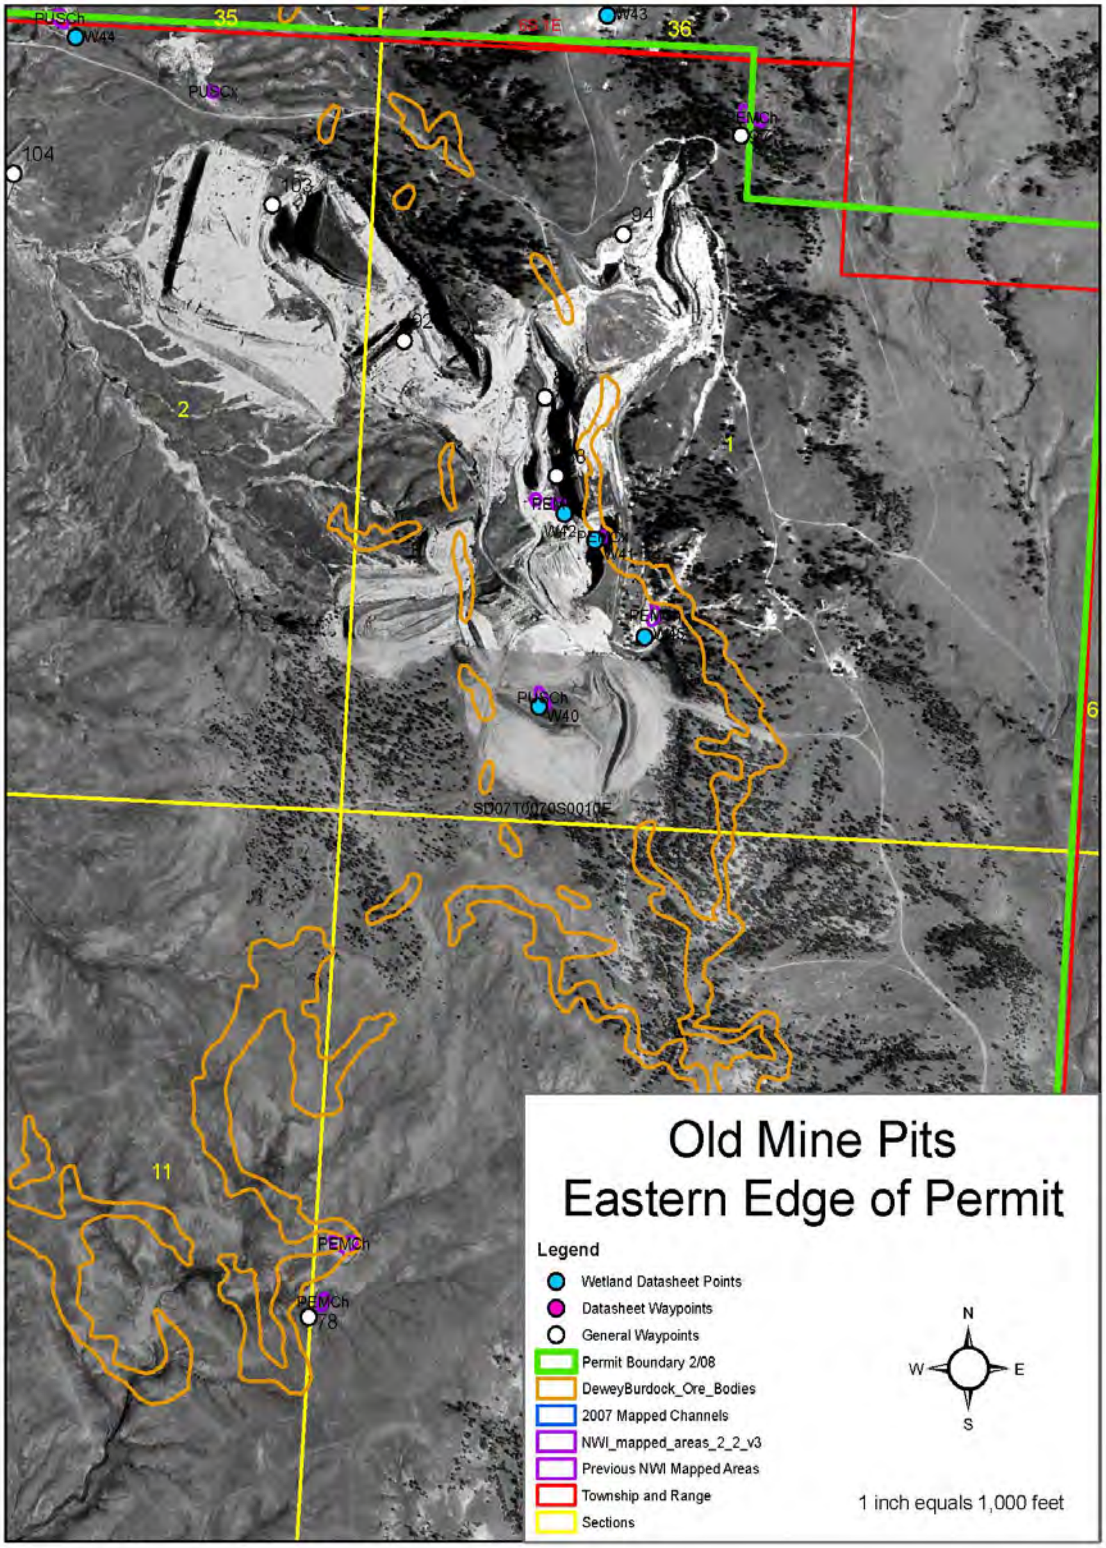

Figure 5.4-3 Old Mine Pits Eastern Edge of Permit

Natural Resources Conservation Service (NRCS) soils mapping for Custer and Fall River Counties, South Dakota, (2007) and BKS soil mapping of the PAA were reviewed for general soils information. Potential wetlands (WoUS) and OWUS were initially identified via review of area maps to include the following:

- 1977 USFWS NWI mapping for the Dewey, Burdock and 21 Quads
- Custer Quad Digital Elevation Model
- Burdock Quad Digital Elevation Model

Wetland indicator categories were identified for each dominant plant species noted through use of the National List of Vascular Plant Species that Occur in Wetlands, 1996 National Summary. Region 4 (North Plains) indicator categories were utilized for the PAA.

Field sample locations and resulting wetland boundaries were recorded with a hand-held Garmin GPS map, 60Cx Global Positioning System (GPS) unit in NAD 1983 UTM Zone 13. BKS provided drafting services for the Proposed Action.

5.4.4.2.2 Wetland Survey Results

The PAA was generally characterized by Big Sagebrush Shrubland, Greasewood Shrubland, and Ponderosa Pine Woodland with pockets of Upland Grassland and Agricultural land, mine pit, Silver Sagebrush Shrubland, Shale Outcrop, or Pass Creek. Beaver Creek had Agricultural land to the south and Greasewood Shrubland and Big Sagebrush Shrubland to the north. Agricultural land comprised 399.83 acres, Greasewood Shrubland comprised 2,252.15 acres and Big Sagebrush Shrubland comprised 2,738.85 acres. Beaver Creek had water present continuously in the drainage and wetland species near the banks. The upper banks were comprised mainly of *Artemisia tridentata* (big sagebrush), *Sarcobatus vermiculatus* (Greasewood), and *Elymus smithii* (Western wheatgrass). The wetland indicator status of these plants are UPL (upland), UPL and FACU (facultative upland) respectively. The Pass Creek comprised of the Cottonwood Gallery vegetation community comprised mainly of *Bromus inermis* (smooth brome), western wheatgrass, and *Populus deltoides* (cottonwood trees). The wetland indicator statuses of these plants are UPL, FACU, and FAC (facultative) respectively. Please refer to Section 5.4.4 for further information regarding the vegetation within the PAA.

The PAA generally occurs on uplands, with inclusions of two main drainages, Beaver Creek and Pass Creek and several depressed areas. Beaver Creek and Pass Creek were evaluated using pedestrian reconnaissance, while the remaining small drainages were evaluated based on existing mapping. Wetlands were identified throughout the Beaver Creek drainage; however Pass Creek only had wetlands present near an old open flowing well close to PAA. Wetlands were also identified in the majority of the old mine pits, as well as depressed areas throughout the PAA. The wetland classification along Beaver Creek was Riverine Lower Perennial Emergent (R2EM) and Palustrine Emergent (PEM) WoUS in Pass Creek and other small drainages. The mine pits were primarily designated as Palustrine Unconsolidated Bottom (PUB) OWUS and depressions were typically PEM or PUB designations.

The proposed project may affect a total of 35.114 acres of R2EM, R4SB7 (Riverine Intermittent Streambed vegetated), and PEM stream channel, Palustrine Aquatic Bed Intermittently Flooded Diked (PABJh), Palustrine Unconsolidated Shore Temporarily Flooded (PUSA), PEM, PUB, PUS, and PEMC (seasonally flooded) isolated ponds, and open water (OW). The acreage of OW consists of approximately 9.451 acres.

The area had previously been mined for uranium through several open pit mines; some of the mines had been filled in with water. One livestock watering tank was identified on the survey.

Soils information for the PAA was obtained by NRCS Web Soil Survey for Custer and Fall River Counties, South Dakota, (2007).
There are two main drainage basins located in the PAA; each of the drainages had different soil types. Beaver Creek had Haverson loam, 0-2 percent slopes throughout the drainage. Pass Creek had Barnum silt loam in the south half of the drainage and Barnum-Winetti complex, 0-6 percent slopes. The old mine pits were also classified as Barnum silt loam and Barnum-Winetti complex.

None of the soil map units were found on the hydric soils list for Fall River County or Custer County, South Dakota.

Table 5.4-17 is a summary list of the wetlands in the PAA along with several details about each wetland, including location, delineation designation, geomorphic setting, comments, and jurisdictional recommendations. Table 5.4-18 provides of summary of the 2007 wetland delineation results.

5.4.4.2.3 Results

Beaver Creek

Beaver Creek is located in the northwest of the PAA in Sections 30, 31, and 32 in T6S, R1E. The entire stretch of Beaver Creek within PAA is designated as a R2EM wetland, for a total of 13.376 acres. Seven data forms were filled out for the variety of lengths in the drainage as well as four photo waypoints. The most common vegetation that was identified along the drainage was Spartina pectinata (prairie cordgrass), Juncus balticus (Baltic rush), and Schoenoplectus pungens (common three-square). These plants have an indicator status of FACW (facultative wet), FACW, and OBL (obligate) respectively.

Pass Creek

Pass Creek is centrally located within the PAA in T7S, R1E in Sections 3, 9, and 10, and T6S, R1E in Section 34. Pass Creek only had wetlands present in Section 9, primarily due to an old open flowing well on the other side of the road outside PAA. The wetland totaled 0.503 acres of PEM, a total of four datasheets were filled out. The common vegetation found within the wetland was prairie cordgrass and common three-square. The remaining drainage was walked and delineated, however no other wetlands were present. Five non-wetland datasheets were filled out and photo points were taken. Refer to Table 5.4-17, Summary of Wetlands within the PAA for more details.

Previously Mapped Wetlands Confirmed as a Non-Wetland

There were several National Wetlands Inventory 1977 previously mapped wetlands that were confirmed as non-wetland or not present during the 2007 field survey. The areas generally lacked hydrophytic vegetation, hydric soils, and hydrology. Most areas had geomorphic position but often lacked another secondary indicator. Datasheets were filled out to confirm no presence of these wetlands and can be found in Table 5.4-17, Summary of Wetlands within the PAA for more details. Previously mapped wetlands that are no longer present do not appear on the map (Exhibit 5.4-2).

Old Mine Pits
There are seven old uranium open pits present within the PAA. Four of the mine pits were classified as non-wetland primarily due to lack of hydrophytic vegetation and/or hydrology presence. Two mine pits located in T7S, R1E in Section 1 were classified as PUB wetlands. The only mine pit in Section 2 was classified as both a PEM and Open Water (OW). The PEM is located along the bank of the pit and OW throughout the rest of the pit. The mine pit in Section 34 T6S R1E was classified as OW and totaled 7.635 acres another small mine pit located at waypoint 92 is Section 1 T7S R1E was classified as OW at 0.452 acres. There were approximately 1.172 acres of wetlands and 9.451 acres of open water within old mine pits in the PAA. Refer to Table 5.4-17, Summary of Wetlands within the PAA for more details.

Depressional Areas and Ponded Areas Identified as Wetlands
All the depressional areas identified as wetlands in 2007 were also previously identified during the 1977 NWI mapping. All of these wetlands are recommended to be non-jurisdictional based on the isolated nature of the wetlands. The wetlands were primarily classified as PEM, PEMC, PABJh, PUS, PUSA and PUB wetlands based primarily on the hydrology conditions of each waypoint. There were approximately 10.292 acres of wetland depressions and ponds present within the PAA. Refer to Table 5.4-17, Summary of Wetlands within the PAA for more details.

Beaver Creek Update
Beaver Creek is likely to have wetlands throughout the entire PAA as it is a major drainage and had a good flow of water when the surveys were conducted in 2007. The boundary change took out 1.956 acres of R2EM wetlands along Beaver Creek in the NW1/4 of Section 31 T6S R1E. The boundary change also added 4.81 acres of R2EM wetlands along Beaver Creek in the SE1/4 of Section 31 T6S R1E and E1/2 of Section 5, the SW1/4 of Section 4 of T7S R1E. The total acreage addition to the wetlands along Beaver Creek was 2.86 acres of R2EM.

Small PEM and PUB isolated wetlands may be found SW of the Beaver Creek Drainage is Section 5, T7S R1E; however accessibility to the area was not present to confirm. There are two depressions that can be seen on the map and based on the 2007 surveys of the PAA the likelihood of the depressions being classified as a wetland is rare.

Pass Creek Update
In 2007, Pass Creek had 0.503 acres of PEM wetlands surveyed along its stretch; however due to the recent boundary change there are now only 0.05 acres of wetlands present on Pass Creek. The boundary change moved the boundary east of W22, and now excludes the three wetland points of W20, W21, and W22. The wetlands present on Pass Creek are primarily due to an old open flowing well on the other side of the road outside PAA.

In 2007, Pass Creek was surveyed from the southern project boundary to the old mine pit and no wetlands were identified except near the spring. No surveys were conducted on Pass Creek in 2008 as the map indicated that the area is likely dry.

Old Mine Pits
No changes to the acreages on the 2007 identified old mine pits wetland occurrences.

Depressional Areas and Ponded Areas Identified as Wetlands
No changes to the acreages on the 2007 depressional areas and ponded areas identified as wetlands. As noted above there may be some isolated PUB or PEM depressional areas SW of Beaver Creek, but accessibility to the area was not present during the 2008 surveys. However, it is unlikely that the areas indicated contain wetlands as the 2007 surveys proved that many of the potential wetlands indicated on the map and NWI no longer existed.

Approved Jurisdictional Determination

A summary the Approved Jurisdictional Determinations from the Department of the U.S. Army, Corps of Engineers (USACOE), Omaha District for 20 sites identified as wetlands associated with the Dewey-Burdock Project is provided in Appendix 5.4-H. Of the 20 sites identified, only four were deemed jurisdictional. They were Beaver Creek, Pass Creek and an ephemeral tributary to each. While it is not anticipated that the PA would require work in any of the jurisdictional waterbodies identified in the JDs, or any other waters of the United States, Powertech (USA) will seek authorization from the USACOE prior to conducting the work.

5.4.4.3 Wildlife

5.4.4.3.1 General Setting

Wildlife and aquatics sampling were conducted by ICF Jones & Stokes, of Gillette, Wyoming from July 2007 through early August 2008 to meet agency requirements of one year of baseline data, and to accommodate changes to the PAA boundary during that period.

Background information on terrestrial vertebrate wildlife species, and aquatic vertebrates and invertebrates in the vicinity of the Proposed Action was obtained from several sources, including records from SDGFP, BLM, USFWS, U.S. Forest Service (USFS), and the original DES prepared by the TVA in 1979. Previous site-specific data for the PA and surrounding perimeter were obtained from those same sources, with current data collected during regular site visits and targeted surveys conducted from July 2007 through early August 2008.

Current baseline wildlife information was collected for the PA from July 2007 through early August 2008. The survey area included the entire PAA (current as of September 2008), with additional surveys conducted on adjacent lands and in nearby riparian areas for certain species of concern. Due to changes in the PAA boundary after completion of the field surveys, a small portion of the northern-most perimeter was not included in the baseline surveys (refer to wildlife map). However, because those surveys were conducted in representative habitats throughout the PAA, and no new habitat types were included in expanded perimeter, it is the professional opinion of ICF Jones & Stokes that no information was lost for any unique or critical data by not having conducted certain surveys in the limited excluded portion of the one-mile perimeter. That area can be included in any future monitoring required by the SDGFP as a condition of future permitting actions, at their discretion.

Survey protocols and timing were developed collaboratively with SDGFP to meet species-specific requirements. The survey area included the PAA and one-mile perimeter for threatened and endangered (T and E) species, bald eagle winter roosts, all nesting raptors, upland game bird leks, and big game. Surveys conducted only in the PAA included other vertebrate species of concern tracked by the SDNHP, as well as bats, small mammals, lagomorphs, prairie dog (Cynomys spp.) colonies, breeding birds, predators, and herptiles (reptiles and amphibians). Aquatic sampling occurred at water gauge stations located in Beaver Creek upstream of the PAA, and in Beaver Creek and the Cheyenne River downstream of the area. In addition to these targeted efforts, incidental observations of all vertebrate wildlife species seen within the PAA were recorded during each site visit during the year-long baseline survey period. Surveys for black-footed ferrets (Mustela nigripes) were not required for this project due to a block clearance issued by the USFWS that includes the entire PAA and vicinity.

All surveys were conducted by qualified biologists using standard field equipment and appropriate field guides. Most observations were recorded from vantage points during pedestrian or vehicular surveys to avoid disturbing wildlife; exceptions included small mammal trapping and aquatic species sampling. Raptor nests, prairie dog colonies, and other features or observation points of special interest were mapped in the field using a hand-held GPS receiver to record the Universal Transverse Mercator (UTM, NAD27) coordinates.

5.4.4.3.2 Big Game

No crucial big game habitats or migration corridors are recognized by the SDGFP in the PAA or surrounding one-mile perimeter. Crucial range is defined as any particular seasonal range or habitat component that has been documented as the determining factor in a population's ability to maintain and reproduce itself at a certain level.

Pronghorn (Antilocapra americana) and mule deer (Odocoileus hemionus) are the only two big game species that regularly occur in the PAA, and both are considered year-round residents. Elk (Cervus elaphus) and white-tailed deer (O. virginianus) are also present in the survey area, but only in small herds. The latter two species can also be seen in the survey area year-round, but may be more common during different times of the year.

The pronghorn is the most common big game species in the Proposed Action survey area, though no species is prevalent. The pronghorn is a browse species and sagebrush-obligate, using shrubs for both forage and cover (Fitzgerald et al. 1994). Pronghorn herds were most often observed in sagebrush stands just beyond the north-central boundary of the PAA during winter 2007-2008. Conversely, herds were widely distributed throughout grassland habitats in the northwestern and southeastern portions of the survey area during spring, summer, and early fall 2008. In June, after the ground and water pools had dried up, water availability became a limiting factor and pronghorn began to move to, and concentrate around, more dependable water sources such as Beaver Creek and livestock tanks, and to draws with more succulent forage.

Mule deer use nearly all habitats, but prefer sagebrush-grassland, rough breaks, and riparian bottomland (Jones et al. 1983). Browse is an important component of the mule deer's diet throughout the year, comprising as much as 60 percent of total intake during autumn, while forbs and grasses typically make up the rest of their diet (Fitzgerald et al. 1994). In the Proposed Action survey area, mule deer were observed as individuals or in small herds in ponderosa pine and cottonwood riparian habitats along Beaver and Pass Creeks, and in the pine breaks along the eastern edge of the PAA. They are considered year-round residents in the survey area.

By nature, elk are shy animals that are less accepting of human disturbance than pronghorn (Fitzgerald et al. 1994) or deer. Elk in the Proposed Action survey area share their range with pronghorn and domestic cattle from spring through fall. Because elk prefer grass to shrubs, the resident herd competes more directly with domestic cattle and wild horses than with pronghorn in the spring and summer months. A herd of six bull elk was observed in the survey area in ponderosa pine habitat on one occasion (June 2008) during the baseline survey period, but local residents report that elk are frequently seen in the pine stands, especially during fall and winter.

White-tailed deer are typically associated with forests, woodlands, and treed galleries along streams (Fitzgerald et al. 1994). Small numbers of white-tailed deer were observed in the Proposed Action survey area during the baseline survey period, predominantly in the cottonwood corridor along Pass Creek in the central portion of the PAA. Most sightings of white-tailed deer were actually in the cottonwood corridor along the Cheyenne River, approximately 2-2.5 miles south of the PAA. This species is considered an uncommon year-round resident in the survey area itself.

5.4.4.3.3 Other Mammals

A variety of small and medium-sized mammalian species have the potential to occur in the Proposed Action survey area, although not all were observed in the PAA itself during the baseline wildlife surveys. These potential species include a variety of predators and furbearers such as the coyote (Canis latrans), red fox (Vulpes vulpes), raccoon (Procyon lotor), bobcat (Lynx rufus), badger (Taxidea taxus), beaver (Castor canadensis), and muskrat (Ondatra zibethicus).

Numerous prey species, including rodents (e.g., mice, rats, voles, gophers, ground squirrels, chipmunks, prairie dogs, etc.), jackrabbits (Lepus spp.), and cottontails (Sylvilagus spp.) can also be found in the Proposed Action survey area. These species are cyclically common and widespread throughout the region, and are important food sources for raptors and other predators. Each of these prey species, with the exception of chipmunks and rats, were either directly observed during the field surveys, or were known to exist through burrow formation or scat. Jackrabbit sightings were uncommon and cottontail sightings were below normal, suggesting these species are currently in a local downward trend. Observations of small mammals occurred most often near Beaver and Pass Creeks, in the northwestern and central portions of the survey area, respectively.

One black-tailed prairie dog (Cynomys ludovicianus) colony is located in the northwestern corner of the PAA, and two others are present in the southwestern portion of the one-mile perimeter. Local ranchers use shooting and other control methods to reduce and/or eradicate prairie dogs from the PAA (private surface) and surrounding private lands.

Other mammal species such as the striped skunk (Mephitis mephitis), porcupine (Erethizon dorsatum), and various weasels (Mustela spp.) inhabit sage-steppe communities, but no sightings or confirmed scat were recorded for these species during the surveys. Infrequent, incidental bat sightings (species unknown) occurred during nocturnal amphibian surveys and spotlighting efforts at targeted ponds in the PAA during the baseline period.

Small mammal trapping was conducted during fall 2007 as part of the baseline survey requirements for the Proposed Action. Trapping occurred in nine transects spread among six habitat types: Upland Grassland, Ponderosa Pine, Greasewood, Cottonwood Gallery, Clay Breaks, and Pine/Sage Edge. Grassland habitats occupy the largest parcels throughout the area, and held four transects; the remaining habitats held one transect each. Each transect included a combination of 20 live traps, 10 snap traps, and 5 pitfall traps. All traps were baited daily, with cotton balls placed in the live and pitfall traps for nesting material. Each transect was run for three consecutive days and nights (per SDGFP). Total trap nights per habitat ranged from 105 to 420 (upland grassland only), with a total of 945 trap nights across all habitats.

The deer mouse (Peromyscus maniculatus) dominated the captures, with only six individuals of other species recorded (Table 5.4-19). Deer mice are known for their ubiquitous presence and generalized habitat use, and these survey results are similar to those from other recent trapping efforts in northwest South Dakota and northeastern Wyoming.

Lagomorph (hares and rabbits) surveys are also a common component of baseline wildlife inventories. Spotlight lagomorph counts were conducted on two consecutive nights in fall 2007. Cottontail abundance was twice that of jackrabbits, though neither count was especially high (Table 5.4-20). Results from lagomorph surveys conducted in northeast Wyoming annually since 1984 indicate that the regional lagomorph population is experiencing a downward trend in its regular cyclic pattern. Although no data is available from the PAA prior to 2007, its proximity to the annual survey area in Wyoming suggests that the population trend is similar in southwestern South Dakota.

Table 5.4-19 Small Mammal Abundance during Trapping within the PAA in September 2007

	Captures per 100 trap-nights*

[1] Survey route totaled 8.2 miles.
[2] Number given is highest count per species from two survey nights.

5.4.4.3.4 Raptors

Raptor species observed during the Proposed Action baseline wildlife surveys included the bald eagle, red-tailed hawk (Buteo jamaicensis), golden eagle (Aquila chrysaetos), ferruginous hawk (Buteo regalis), northern harrier (Circus cyaneus), American kestrel (Falco sparverius), turkey vulture (Cathartes aura), Cooper's hawk (Accipiter cooperii), rough-legged hawk (Buteo lagopus), merlin (Falco columbarius), great horned owl (Bubo virginianus), and long-eared owl (Asio otus). Other raptor species could also occur in the survey area, particularly as seasonal migrants, but were not seen during the 2007 and 2008 inventories.

Raptor sightings were recorded frequently throughout the Proposed Action survey area during 2007 and 2008 in ponderosa pine, cottonwood riparian, and grassland habitats. Observations were most concentrated in proximity to Beaver Creek and Pass Creek, perhaps because of prey availability due to the presence of water and better vegetative cover along those drainages. Raptors were observed hunting, perching on nest trees, power poles, and topographic features, nest tending, incubating, and exhibiting nest defense. The bald eagle, red-tailed hawk, American kestrel, and northern harrier were the most commonly seen raptor species in the area. Raptor sightings for those species were recorded with regularity during all four seasons during the baseline survey period, though some of those species may leave the area under harsher winter conditions.

Biologists watched for active raptor nests and breeding behavior (territory defense, courtship flights, prey deliveries, etc.) during all site visits within the breeding season. Additional nest searches were conducted concurrent with other surveys completed during the non-breeding season. Nests were monitored from a distance using binoculars and a spotting scope early in the nesting season to avoid impacting active nests. All active nests were monitored throughout the breeding season to determine their success and production level.

Five confirmed, intact (i.e., material present) raptor nests and one potential nest site were documented in the PAA during the 2007-2008 baseline survey period; two additional nests were recorded in the one-mile survey perimeter (see Wildlife Features map). All eight nests are listed in Table 5.4-21, including their locations, and their status and productivity in 2008. Three raptor species tracked by the SDNHP nested in the PAA. The bald eagle and long-eared owl (*Asio otus*) successfully nested within the PAA. A merlin (*Falco columbarius*) was recorded at a potential nest site in the pine breaks east of the current License boundary. The bird exhibited defensive behavior near the nest site, but no young or signs of active use (e.g., droppings, prey remains, egg shells, etc.) were recorded there.

Table 5.4-21 Raptor Nest Locations and Activity in and Within One Mile of the PAA during Baseline Wildlife Surveys from mid-July 2007 through early August 2008

Species[1,2]	¼ Section	Township/Range	Habitat	Status	Location
LEOW	**SESW 35**	**6 South/1 East**	**Ponderosa Pine**	**1+ owl fledged**	**Permit area**
RTHA (2 nests)	SENE 29	6 South/1 East	Ponderosa Pine	1 hawk fledged	Permit area
RTHA	SESW34	6 South/1 East	Cottonwood-riparian	2 hawks fledged	Permit area
BAEA	**Mid-SW 30**	**6 South/1 East**	**Cottonwood-riparian**	**1 eagle fledged**	**Permit area**

GHOW	SWNE 5	7 South/1 East	Lone, live cottonwood tree	Status unknown[3]	Permit area
Unk Buteo	NESW 28	41 North/60 West (Wyoming)	Lone, dead cottonwood tree	Inactive	1-mile perimeter

[1] **Bold** species are tracked by the South Dakota Natural Heritage Program – South Dakota Department of Game, Fish and Parks (SDGFP web page, last updated September 2, 2008).
[2] Species Codes:
BAEA = Bald eagle
GHOW = Great horned owl
LEOW = Long-eared owl
MERL = Merlin
RTHA = Red-tailed hawk
Unk Buteo = Unknown *Buteo* (soaring hawks) species
[3] One adult GHOW was observed in the nest tree, but no chicks, feathers, droppings, or prey items were observed in or on the nest, or on the ground under the nest.

5.4.4.3.5 Upland Game Birds

The wild turkey (*Meleagris gallopavo*) and mourning dove (*Zenaida macroura*) were the only upland game bird species observed in the Proposed Action survey area during baseline inventories conducted from July 2007 to August 2008. Both species are relatively common and occur in a variety of woodland and open habitats in the PAA.

Three grouse species could potentially occur in the PAA (license area and one-mile perimeter): the greater sage-grouse (*Centrocercus urophasianus*), sharp-tailed grouse (*Tympanuchus phasianellus*), and ruffed grouse (*Bonasa umbellus*). The greater sage-grouse is a species of great concern throughout the west, and is considered a “landscape species” due to its use of wide expanses of sagebrush as primary habitat during each phase of its life cycle. Searches for grouse leks were completed between April 7 and May 12, 2008. Surveys were conducted between first light and approximately one hour after sunrise. Biologists searched for displaying grouse by driving through the PAA and one-mile perimeter, and making frequent stops at vantage points to scan and listen for displaying birds. Although sage-grouse were historically recorded in the general vicinity (TVA DES 1979), no leks have been documented by agency biologists within 6 miles of the PAA in recent years. No grouse were observed during the entire year-long baseline survey period for this project. Potential habitat for sage-grouse is present, but only in small stands of sage surrounded by grasslands and pine breaks; such habitat is not conducive to supporting a population of sage-grouse.

5.4.4.3.6 Other Birds

Lists of avian species tracked by the SDNHP were obtained from Mr. S. Michals (SDGFP) in July 2007 and the SDGFP website in September 2008. Biologists watched for all vertebrate species of concern during each site visit to the PAA during the year-long baseline survey period. All observations were recorded, including notes on species, number of individuals, age and sex (when possible), location, habitat, and activity. Three species of special interest (i.e., tracked by the SDNHP) were observed while conducting other surveys during the baseline inventory period: the Cooper’s hawk (*Accipiter cooperii*), golden eagle (*Aquila chrysaetos*), and Clark’s nutcracker (*Nucifraga columbiana*). All three species were briefly observed flying over the PAA, but no known nesting or other targeted use was recorded by these species.

In addition to those incidental observations, targeted surveys for breeding birds (primarily passerines) were conducted in the same habitats and along the same general transects within the PAA as the small mammal trapping. Four transects were surveyed in Upland Grassland, and one each in the remaining five habitat types. Breeding bird surveys were conducted using belt transects measuring 100 m wide by 1,000 m long. Transects were surveyed by slowly walking through the center of each line and stopping at least every 50 m to watch and listen for birds. Individuals observed while walking were also recorded, with efforts made to avoid double counting birds. Each transect was surveyed on three consecutive mornings in June 2008. To reduce bias, surveys started in a different habitat type each morning. Surveys began between dawn and sunrise, and were completed within four hours. All birds were identified to species. Flyovers and birds seen and heard beyond the transect boundaries were recorded as incidentals, but were not included in the analysis. Surveys were not conducted during inclement weather (precipitation, moderate to heavy winds, etc.).

Weather conditions during all surveys were mostly calm and clear, with a light breeze and approximately 25 percent high, thin cloud cover. Thirty-six species were observed within the breeding bird transects during spring 2008, with two additional unknown species logged (Table 5.4-22). The western meadowlark (*Sturnella neglecta*) was the most common species, followed by the mourning dove. The dove was the only species recorded in all six habitat types. The long-billed curlew (*Numenius americanus*) was the only species of the 36 observed that is tracked by the SDNHP. As expected, several species were associated with specific habitat types. For example, the curlew was only seen in the grassland transects (Table 5.4-22). Likewise, several species typically associated with trees were only observed in or immediately adjacent to the Cottonwood Gallery or Ponderosa Pine transects: the chipping sparrow (*Spizella passerina*), mountain bluebird (*Sialia currucoides*), black-capped chickadee (*Poecile atricapillus*), and yellow-rumped warbler (*Dendroica coronata*), among others. Similar associations were noted between other species and habitats.

5.4.4.3.7 Waterfowl, Shorebirds

Under natural conditions, the PAA provides limited seasonal habitat for waterfowl and shorebirds. As described previously, natural aquatic habitats in the PAA occur mainly in Beaver Creek and Pass Creek, with a few scattered stock reservoirs also present. Because of the limited precipitation in the area, such habitats are available primarily during the spring migration period, with less reliable nesting and brood-rearing habitat in the area.

Although specific surveys for waterfowl and shorebirds were not required for the uranium project, biologists recorded all birds seen during the year-long survey period. Eight species associated specifically with water and/or wetlands were observed during the baseline inventories: the American white pelican (*Pelecanus erythrorhynchos*), great blue heron (*Ardea herodias*), Canada goose (*Branta canadensis*), mallard (*Anas platyrhynchos*), American wigeon (*Anas americana*), killdeer (*Charadrius vociferus*), long-billed curlew, and upland sandpiper (*Bartramia longicauda*). The pelican, heron, and curlew are tracked by the SDNHP.

5.4.4.3.8 Reptiles and Amphibians

The aquatic resources present within the PAA and surrounding perimeter have been thoroughly described in previous sections. Water is a limiting factor throughout the survey area and surrounding lands, with only one perennial stream passing through the western extent of the PAA and all other natural flow categorized as intermittent or ephemeral. Even the perennial Beaver Creek experiences extended periods of low volume and flow in most years. The creeks are meandering streams with extended reaches of muddy soil substrates and intermittent riparian vegetation. Aquatic species are not locally common inhabitants of the PAA. The lack of deep-water habitat and multiple perennial water sources limits the presence of fish, and decreases the potential for other aquatic species to exist.

Three aquatic or semi-aquatic amphibian species and one aquatic reptile were recorded during the 2007 and 2008 surveys PAA: the boreal chorus frog (*Pseudacris triseriata*), Woodhouse's toad (*Bufo woodhousei*), great plains toad (*B. cognatus*), and western painted turtle (*Chrysemys picta*). All four species were heard and/or seen in Beaver Creek as it flows through the western portion of the PAA, or near stock reservoirs. All four species are common to the PAA, and the region as a whole. One additional aquatic reptile was recorded in the perimeter surrounding the PAA, the western spiny softshell (*Trionyx spiniferus*). That observation also occurred in Beaver Creek, during the July 2008 fisheries sampling session.

Lizards (species unknown) were often observed sunning themselves on rocks and on sandy soil in the summer months during all except the early morning hours. These sightings were widespread throughout the survey area, with observations increasing as the summer progressed and the days got hotter. The shed remains of a snake skin were found in the north central portion of the survey perimeter in early May, 2007. The skin was at the base of a rock outcrop and looked as though it may have belonged to a bullsnake (*Pituophis cantenifer*).

5.4.4.4 Threatened, Endangered, or Candidate Species and Species Tracked by SDNHP

5.4.4.4.1 Federally Listed Species

No federally listed vertebrate species were documented in the PA survey area (current PAA and one-mile perimeter) during the year-long survey period. The black-footed ferret was the only federal T&E vertebrate species that could potentially occur in the PAA (http://www.sdgfp.info/Wildlife/Diversity/RareAnimal.htm 9/25/08). The U.S. Fish and Wildlife Service issued a block-clearance for ferrets throughout the entire state of South Dakota in recent years, including the Proposed Action survey area in extreme southwestern Custer County and northwestern Fall River County (C. Bessken, USFWS Biologist-SD, personal communication to G. McKee, Jones & Stokes, July 2, 2008). The only exception to that clearance is in Custer State Park in northern Custer County. Although ferret surveys were not required for the Proposed Action, they were conducted in the general vicinity of the PAA during monitoring performed for the TVA DES in fall 1977 (TVA DES 1979). No ferrets or evidence of their presence (e.g., trenching, tracks, or scat) were observed during those historic surveys, or during the recent project survey period. As described previously, one black-tailed prairie dog colony is located in the northwestern corner of the PAA, and two others are present in the southwestern portion of the one-mile perimeter. Local ranchers use shooting and other control methods to reduce and/or eradicate prairie dogs from the PAA (private surface) and surrounding private lands.

5.4.4.4.2 State Listed Species
The State of South Dakota lists 23 vertebrate species as threatened or endangered:

- Threatened: 4 fish, 4 birds, 2 mammals, 1 snake, and 1 turtle
- Endangered: 5 fish, 4 birds, 1 mammal, and 1 snake

The current list of these state species is available on the SDGFP website: http://www.sdgfp.info/Wildlife/Diversity/TES.htm.

Only 1 of those 23 state-level T&E species was documented within the PAA or one-mile perimeter during the survey period (mid-July 2007 through early August 2008). Although the bald eagle was removed from the federal listing process in August 2007, it is still considered as a threatened species at the state level in South Dakota. Bald eagles were repeatedly observed along Beaver Creek in the western portion of the proposed permit area and perimeter during winter roost surveys conducted in late 2007 and early 2008. One active bald eagle nest is located in the northwestern portion of the revised permit area in mid-SW¼ Section 30, Township 6 South, Range 1 East. The nest is in a cottonwood tree along Beaver Creek. The nest fledged one young in 2008.

A northern river otter (*Lontra canadensis*) carcass was unexpectedly discovered at the upstream fisheries sampling point along the Wyoming reach of Beaver Creek in April 2008. The upstream Beaver Creek sampling station (BVC04) was located just east of Highway 85 where it crosses Beaver Creek south of milepost 212 south of Newcastle, Weston County, Wyoming, approximately 12 stream miles (3 linear miles) northwest of the PAA boundary. The otter may have come downstream from Wyoming or upstream from the Cheyenne River during the flooding that occurred in early April. The cause of death was not apparent. The carcass was gone by the July sampling period, presumably washed back downstream with the next flood event. Otters are listed as threatened by the State of South Dakota, and are tracked by the SDNHP.

5.4.4.4.3 Species Tracked by SDNHP
As described in previous sections, current lists of other vertebrate species of interest or concern tracked by the SDNHP were obtained from SDGFP through personal contacts (July 2007) and from the agency's website (September 2008).

Six vertebrate sensitive species or species of local concern other than the bald eagle were documented within the current (September 2008 configuration) PAA during the baseline survey period: the long-billed curlew, great blue heron, golden eagle, Cooper's hawk, American white pelican, and long-eared owl. The long-eared owl and curlew are known or are suspected to have nested in the permit area, based on evidence (young present) or persistent defensive behavior, respectively. The heron, golden eagle, Cooper's hawk, and pelican were merely observed flying over the area; those four species were recorded only once each.

These six species of special interest are considered as secure populations within their respective overall ranges, though one or more could be less common in parts of a given range, especially in the periphery. Likewise, all six are considered to be either rare and local throughout their statewide ranges, or locally abundant in restricted portions of those ranges.

Three additional vertebrate species of concern were documented at least once each in the one-mile perimeter: the merlin, Clark's nutcracker, and plains topminnow (*Fundulus sciadicus*). The birds were described in preceding sections of this document. The topminnow was captured during fisheries sampling efforts in Beaver Creek, beyond all permit boundary outlines, in July 2008. Additional information about those survey efforts and results is presented in Aquatic Resources, below.

5.4.4.5 Aquatic Resources

The fisheries sampling locations correlated with water sampling stations that were selected by a South Dakota permitting contractor for the Proposed Action and approved by SDGFP. That contractor monitored the water stations on a monthly basis for at least one year prior to this licensing application. This co-sampling effort was intended to provide information regarding stream flow and other physical characteristics relative to fish and macro-invertebrate composition.

5.4.4.5.1 Aquatic Species and Habitats

5.4.4.5.1.1 Aquatic Species and Habitats-Survey Methods

Because Beaver Creek is the only perennial stream in the PAA, and is the receiving water for drainage from the portions of the PAA identified for proposed future ISL activities, it was the focus of aquatic habitat monitoring efforts conducted for this project. Some sampling was also conducted in the Cheyenne River downstream of the PAA to obtain additional site data. Beaver Creek is listed as impaired under Section 303(d) of the federal Clean Water Act for the following constituents: oil, specific conductivity, temperature, total dissolved solids, and total suspended solids (EPA 2008).

Baseline monitoring stations were located at sites that were previously established as water quality monitoring locations on Beaver Creek and the Cheyenne River. Using these sites allows a comparison with past and ongoing water quality records. One site (BVC04) is located upstream and the other (BVC01) is downstream of the proposed ISL activities (see Figure 5.1-12). Fish sampling for species, abundance, and radiological testing was conducted at both Beaver Creek sites, and at a site on the Cheyenne River downstream of the Beaver Creek confluence (site CHR05).

Baseline sampling of aquatic habitat, benthic macro-invertebrates, and fish was conducted according to protocols developed by the South Dakota Department of Environment and Natural Resources (SDDENR 2002) and the SDPFG (S. Michals, personal communication 2008). Aquatic data collected at the two Beaver Creek sites during the baseline sampling included: stream habitat description; aquatic benthic macro-invertebrate community composition; the variety, condition, and relative abundance of fish species; and radiological analysis of fish collected. As indicated, fish sampling also occurred at CHR05, though SDGFP did not require the other aquatic sampling efforts to be conducted at that location.

Habitat, invertebrate, and fish sampling was conducted during spring (April) and summer (July) conditions in 2008 to provide a baseline for semi-annual monitoring described in NRC Guide 4.14 (NRC 1990). This timing was selected to capture seasonal differences, including high and base flow conditions. However, the late spring and early summer of 2008 were unusually wet and, as a result, the flow during both seasonal events was similar. Consequently, neither sampling effort represented the low summer flow conditions that have typically occurred at these sites in recent years (M. Hollenbeck, personal communication 2008).

The habitat description and invertebrate collection efforts followed the SDDENR protocol (SDDENR 2002). Eleven cross-section transects were established at equidistant intervals from the downstream end of each sample site. The longitudinal distance of each survey reach was established as the distance equal to 30 average channel widths as determined by 10 preliminary width measurements.

Fish sampling was accomplished by blocking and seining a 100-m survey reach downstream of each sample site, according to SDPFG guidelines (S. Michals, personal communication 2008). Due to obstacles in the stream, it was not feasible to seine an entire reach in one sweep, so three separate sweeps were made at a given sample site and fish were collected on shore at three locations within each 100-m reach. All fish captured were identified, counted, measured, and weighed. Individuals that were less than 100 millimeters (mm) in length were combined for a composite weight by species.

Numerous fish were collected for radiological testing during each of the spring and summer flow sampling events. The initial target at each sample site was six individual fish, preferably from six different species (i.e., 6 fish per sample site, 18 total fish), though fewer fish were retained if the target was not achieved. Many of the specimens collected in April 2008 contained no detectable Uranium. In an effort to improve the protocol to better represent conditions in sampled fish populations, up to five individuals of each of six species (i.e., 30 fish per sample site, 90 total fish) were collected in July (when available in the catch) and processed for radiology.

Live fish were bagged, frozen, and kept frozen until they were analyzed for the following:

- Uranium (mg/kg)
- Uranium (µCi/kg)
- Thorium-230 (µCi/kg)
- Radium-226 (µCi/kg)
- Lead-210 (µCi/kg)
- Polonium-210 (µCi/kg)

These analytes are specified in NRC Guide 4.14. Analysis was conducted by Energy Laboratories Inc., in Casper, Wyoming. Lab results are included in Appendix 5.4-I, and are summarized in Table 5.4-23.

5.4.4.5.1.2 Aquatic Species and Habitat-Survey Results

5.4.4.5.1.2.1.1 Habitat

Compiled habitat data forms may be found in Appendix 5.4-J. Summaries of results by site are described below.

Site BVC04

Site BVC04 is located downstream of the Old Highway 85 bridge over Beaver Creek in Weston County, WY (see Figure 5.1-12). This site was selected as the background site as it is upstream of all proposed activity. At BVC04, Beaver Creek is a low gradient prairie stream that is deeply incised in places, is subject to large fluctuations in flow, and shows significant evidence of active erosion (bank slumping, bare soil) and sediment deposition on stream banks and in slow moving pools.

April

The preliminary average channel width at BVC04 was 7.35 m. Sample transects were located 18.5 m apart, with a total surveyed reach length of 185 m. During the April habitat survey, water temperature varied from 7.0 degrees Celsius (C) to 16.0 degrees C, indicating that stream temperature is highly variable during the day. In general, riparian vegetation is limited to herbaceous and short shrubs, with only occasional trees. With the exception of the bridge, there was no shade present in the center of the channel. As a result, the creek is subject to substantial solar heating during the day. Water was clear during the survey, although specific conductivity was high (5,109 µS/cm), indicating a high concentration of dissolved solids typical of prairie streams in this region. Discharge at BVC04 was 7.31 cfs on April 14.

Within the BVC04 survey reach, habitat included two large pools, two glides, and 3 riffles. The total length of riffles was 54.6 m.

Beaver Creek carries a heavy sediment load during high flow, resulting in a deep layer (up to 2 feet) of fine silt deposited in pools. Silt dominates the sediment composition of the reach, although sand, gravel and cobbles dominate the substrate of the faster moving riffle and glide areas. The cumulative and proportional particle distribution of sediment in the BVC04 reach during the April survey is shown in Figure 5.4-4. This distribution indicates a predominance of silt and sand, with gravel in the riffle areas. Large wood in the reach was located in riffle and glide areas and was generally comprised of small (0.1- to 0.25-m diameter) pieces in the portion of the channel between the wetted channel and the bank full elevation.

Beaver Creek is significantly incised. Bank slumpage was observed at eight transects and erosion at ten of the eleven transects in this reach. The wetted stream width during the survey was 4.2 to 10.7 m; bank-full width ranged from 5.3 to 11.3 m; and the width at the top of bank was 10.7 to 17.1 m. Bank height was up to 2.0 m. Riparian land use is rangeland with no riparian buffer, cattle have access to the stream, especially in the vicinity of the bridge. Woody vegetation has probably been sparse along Beaver Creek stream banks for many years, which may have contributed to channel down-cutting and erosion, and a general lack of large woody debris and cover in the channel. Examples of channel dimensions in pool, riffle, and run habitat types of the upstream (BVC04) site are shown in Figures 5.4-5, 5.4-6, and 5.4-7, below.

As mentioned previously, pools contained a large volume of silt. This silt reduces the depth and volume of the pools, reducing the quality and quantity of available fish habitat. Due to pool filling and lack of cover, pool quality is poor.

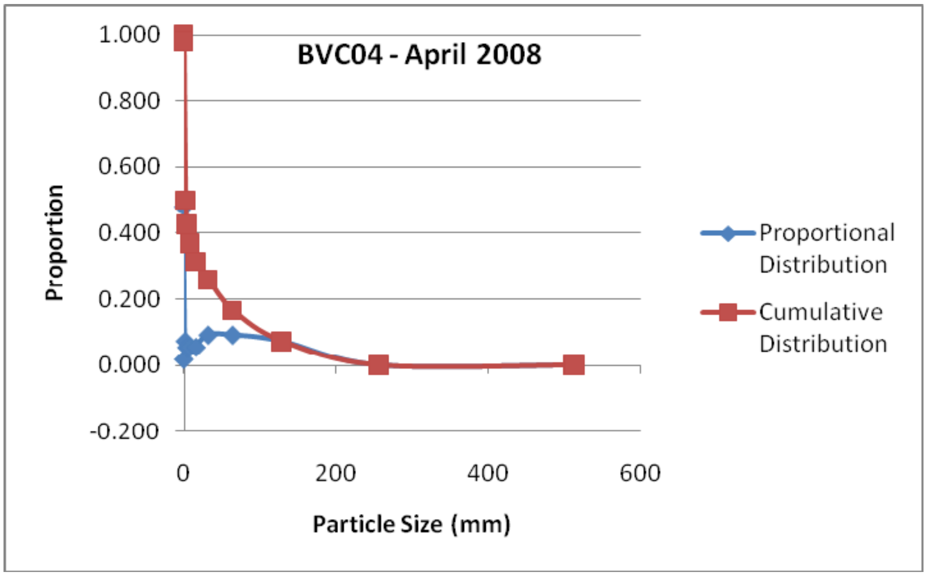

Figure 5.4-4 Cumulative and Proportional Sediment Particle Distribution at Site BVC04, Transects 1 through 11 Combined, April 2008

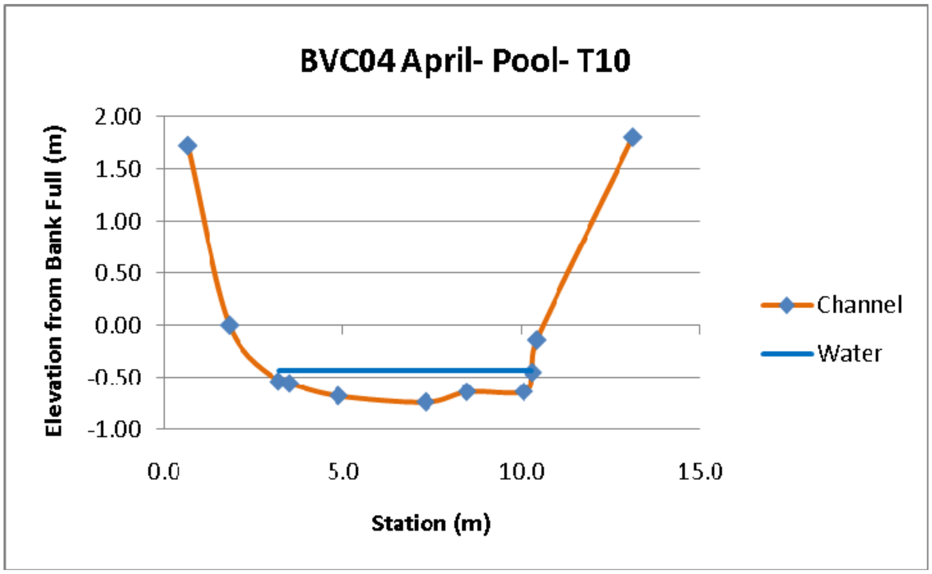

Figure 5.4-5 Channel Dimensions in Pool Habitat, Transect 10

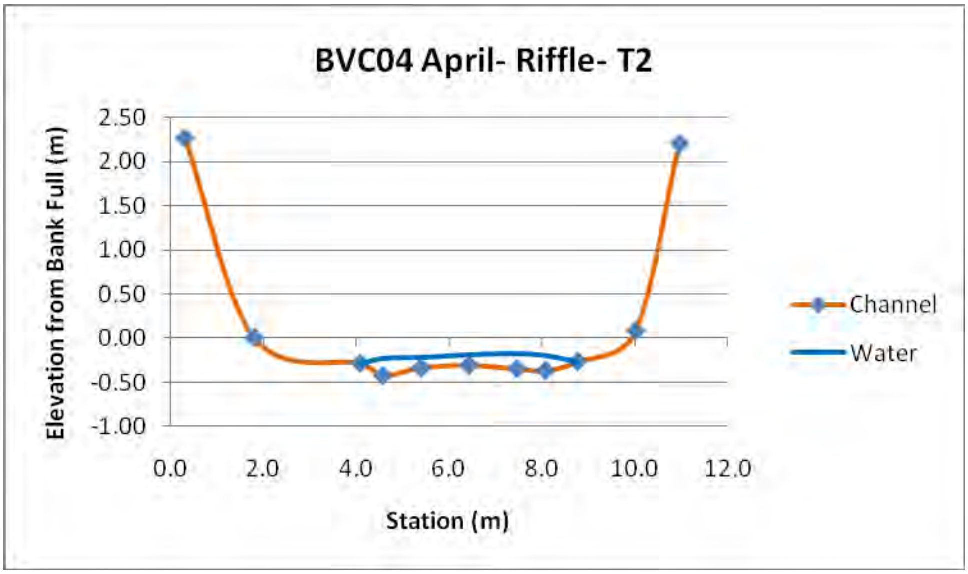

Figure 5.4-6 Channel Dimensions in Riffle Habitat, Transect 2

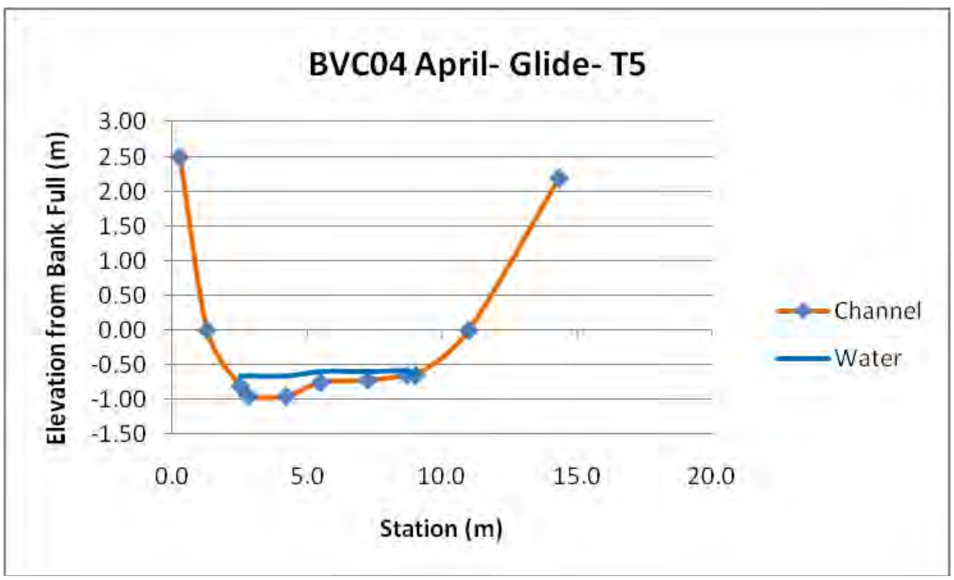

Figure 5.4-7 Channel Dimensions in Glide Habitat, Transect 5

July

In July 2008, the channel dimensions were essentially the same as measured during April, with some localized changes. Between the April and July field visits Beaver Creek experienced high flows that appeared to have resulted in somewhat less fine sediment in the pools, and transport of woody debris out of the survey reach. Stream discharge in July was 12.3 cfs, approximately 5 cfs higher than in April. The average wetted width measured was 6.9 m in April and 7.5 min July.

The July air temperature reached 25 degrees to 35 degrees C and water temperatures were quite warm at 23 degrees C to 24 degrees C. As during April, riparian vegetation was limited to herbaceous and short shrubs, with only occasional trees. Shade along the banks was greater in July, since trees were generally bare in April and fully leafed-out in July. However, most of the stream channel itself was unshaded during both site visits indicating a high degree of solar warming is typical in Beaver Creek.

Within the BVC04 survey reach, habitat included one pool, three glides, and three riffles. The total length of riffles was 59.9, although two riffle segments ran to either side of an island. If these two are considered together, the riffle length measured 43.9 m.

As described under spring conditions, fine silt dominated the sediment composition of the reach and filled the larger part of the pools in at this site. Sand, gravel and cobbles dominate the substrate of the faster moving riffle and glides. The cumulative and proportional particle distribution of sediment for the BVC04 reach during the summer survey is shown in Figure 5.4-8 demonstrating a slightly higher proportion of gravel in the overall substrate composition than in April.

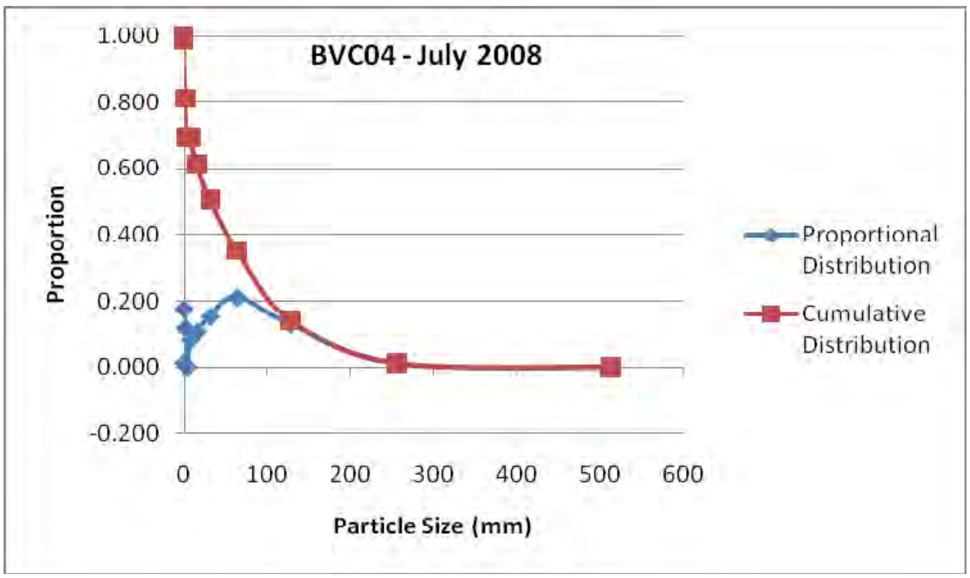

Figure 5.4-8 Cumulative Sediment Particle Distribution at Site BVC04, Transects 1 through 11 Combined during July

Large wood in the reach was essentially absent in July. Small pieces that had been present in April apparently were washed out of the survey reach during the peak flows that occurred in June.

The wetted stream width during the summer survey was 4.3 to 10.1 m; bank-full width ranged from 6.0 to 11.2 m; and the width at the top of bank was 15.0 to 21.0 m. Bank height was 2.1 to 3.9 m.

As mentioned previously, pools contained a large volume of silt. This silt reduces the depth and volume of the pools, reducing the quality and quantity of available fish habitat. Due to pool filling and lack of cover, pool quality is poor.

Site BVC01

Site BVC01 is located upstream of the Argentine Road bridge over Beaver Creek in Fall County, SD. This site was selected as the test site as it is downstream of most proposed production activity and all proposed process water land application sites.

At BVC01, Beaver Creek is still a low gradient, incised prairie stream as it is at BVC04. However, the stream gradient is slightly higher and banks are generally lower. Riparian habitat along BVC01 is more actively managed for cattle grazing than BVC04 and there are fewer trees and shrubs and more grass at

BVC01 than at BVC04. Fine sediment was present in pools. However, there appeared to be less fine sediment in July indicating that high flows transported sediment out of this reach.

April
The preliminary average channel width at BVC01 was 7.35 m. Sample transects were located 22 m apart, with a total surveyed reach length of 220 m.

During the April habitat and fish surveys, water temperature varied from 11.8 degrees C to 16.9 degrees C, indicating that stream temperature at this site is also variable during the day. As was the case at site BVC04, riparian vegetation at BVC01 was limited to herbaceous and short shrubs, with only a single boxelder tree in the survey reach. With the exception of the bridge, there was no shade present in the center of the channel and the creek is subject to substantial solar heating during the day.

Water was clear during the survey, although specific conductivity was high (7,186 µS/cm); somewhat higher than observed at BVC04. Discharge at BVC01 was 5.08 cfs on April 14, 2008.

Within the BVC01 survey reach, habitat included three pools, two glides, and three riffles. The total length of riffles was 28 m.

Overall, gravel dominated the sediment composition of the BVC01 reach. The cumulative and proportional particle distribution of sediment for the BVC01 reach during the April survey is shown in Figure 5.4-9. This distribution indicates a predominance of gravel with some fine sediment. The fine sediment was primarily confined to pool areas.

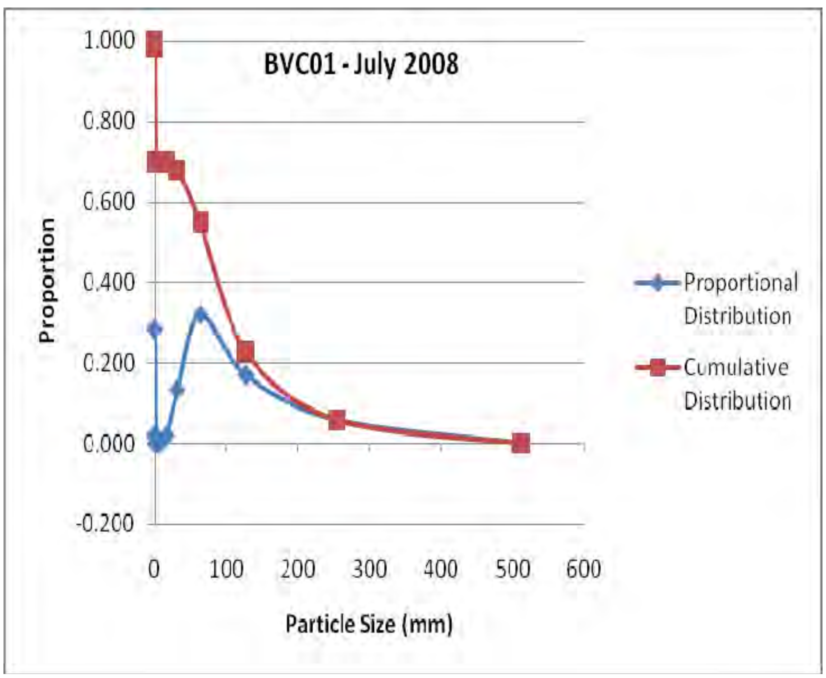

Figure 5.4-9 Cumulative and Proportional Sediment Particle Distribution at Site BVC01, Transects 1 through 11 Combined, April 2008

Beaver Creek is significantly incised along the BVC01 reach, although bank height was generally lower than at the upstream (BVC04) site. Bank slumpage was observed at nine transects and erosion at seven of the eleven transects in this reach. The wetted stream width during the April survey was 3.5 to 7.8 m; bank-full width ranged from 6.5 to 10.2 m; and the width at the top of bank was 12.0 to 17.4 m. Bank height was 1.3 to 2.0 m. Riparian land use is rangeland with no riparian buffer, cattle have access to the stream, especially in the vicinity of the bridge and transect 1. Woody vegetation is nearly absent from the vicinity of BVC01 and no woody debris was observed in the BVC01 survey reach.

Examples of channel dimensions in pool, riffle, and run habitat types are shown in Figures 5.4-10, 5.4-11, and 5.4-12 below.

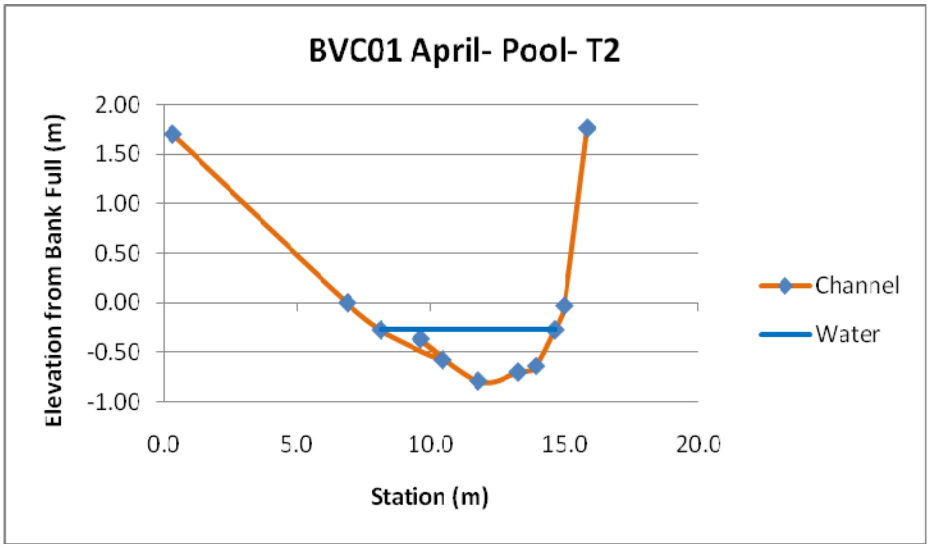

Figure 5.4-10 Channel Dimensions in Pool Habitat, Transect 2

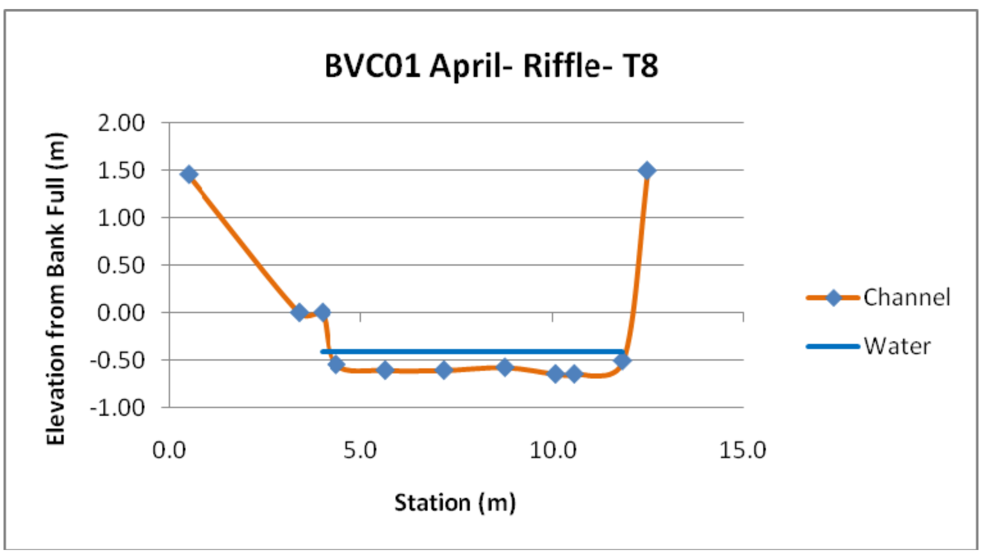

Figure 5.4-11 Channel Dimensions in Riffle Habitat, Transect 8

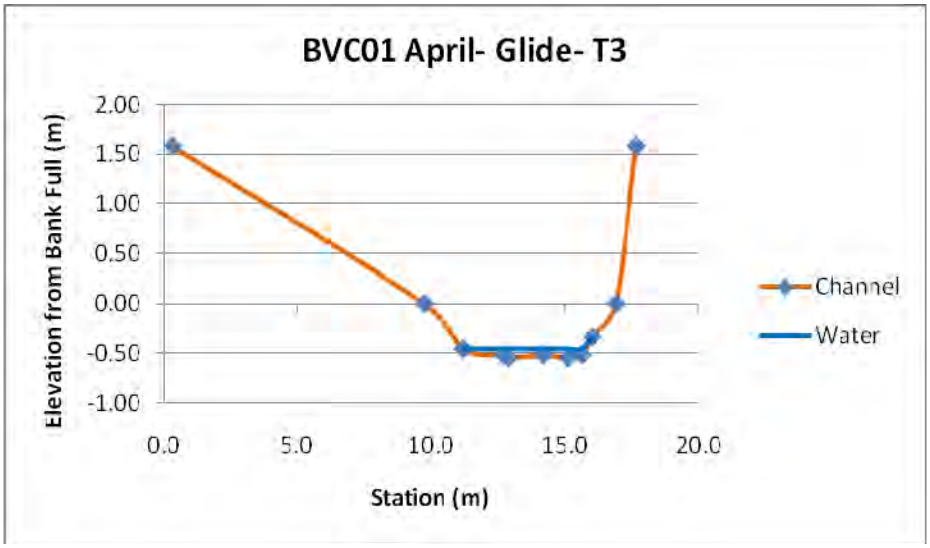

Figure 5.4-12 Channel Dimensions in Glide Habitat, Transect 3

Pools in reach BVC01 were not as deep or long as those in BVC04 and therefore were less conducive to fine sediment deposition. Due to shallow pool depth and lack of cover, pool quality was poor.

July

In July, 2008, the channel dimensions were essentially the same as measured during April, with some localized changes. The high flows that Beaver Creek experienced between the April and July field visits appeared to have resulted in somewhat less fine sediment in the pools. Stream discharge in July was 7.5 cfs, approximately 48 percent higher than in April. In both April and July, discharge was higher at the upstream site (BVC04) than at the downstream site (BVC01). The average wetted width 6.2 m in April and 7.5 m in July.

In July the air temperature at BVC01 a water temperatures of 24 degrees C was recorded at 9:20 am. Although trees were generally bare in April and fully leafed-out in July, the one tree in the riparian buffer was too far from the stream to provide shade to the wetted portion of the channel.

Within the BVC01 survey reach, habitat included two pools, one glide, and two riffles during July. The total length of riffles was 70.8 m. This represented a change from what was observed in April that was due to increased flow and probably some redistribution of gravel substrate in the channel during high flows.

In contrast to April conditions, very little silt was observed within BVC01 during July. Where fine sediment was present it was restricted to slow moving water in pools and along banks. The cumulative and proportional particle distribution of sediment for the BVC01 reach during the summer survey is shown in Figure 5.4.13, demonstrating the dominance of gravel in the particle size distribution.

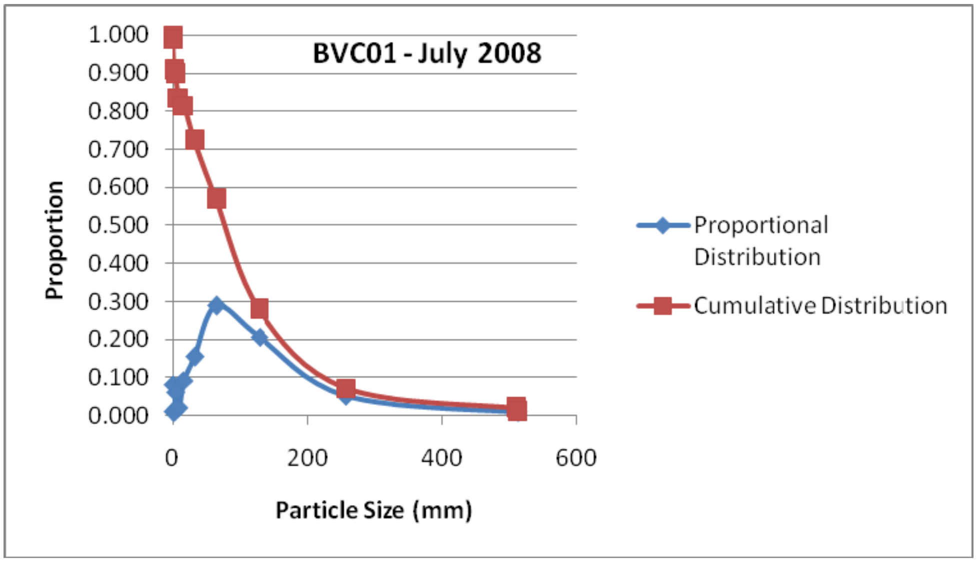

Figure 5.4-13 Cumulative Sediment Particle Distribution at Site BVC01, Transects 1 through 11 Combined during July

Large wood in the reach was essentially absent in July as in April.

The wetted stream width during the summer survey was 4.1 to 8.2 m; bank-full width ranged from 6.8 to 11.3 m; and the width at the top of bank was 12.6 to 18.9 m. Bank height was 1.5 to 2.8 m.

As mentioned previously, pools were considered poor due to lack of depth and cover. Emergent rushes (Juncus spp.) and submerged stonewort (Chara spp.) were observed growing along the banks in pools during the July survey providing some cover for small fish and substrate for aquatic invertebrates.

5.4.4.5.1.2.2 Habitat/Species Relationships

Benthic Invertebrates

Benthic invertebrates can be useful indicators of habitat quality, providing an index of quality that is integrated over time. Different taxa of aquatic invertebrates (primarily insects, crustaceans, and mollusks) exhibit different habitat requirements, feeding strategies, and tolerances to environmental perturbation. Therefore, there are several metrics of benthic invertebrate community composition that are indicative of aquatic habitat quality. Several of the most indicative and most commonly described of these metrics are summarized in Table 5.4-24.

The invertebrate communities sampled indicate poor habitat conditions in Beaver Creek. The counts of each taxa are shown in Table 5.4-25, and a synopsis of the Community composition metrics is shown in Table 5.4-26. The total number of invertebrates and the taxonomic richness (number of species) were both very low at both Beaver Creek sites. Ephemeroptera (mayflies) and plecoptera (stoneflies) were absent from both sites, indicating an impaired condition. Most taxa collected were moderately tolerant taxa. One individual of a sensitive taxa, Lepidostoma, and one individual of a very tolerant taxa, Culiciodes, were collected at the downstream site (BVC01) in April. All other taxa collected are considered moderately tolerant.

The downstream site, BVC01, had very low abundance, particularly in the July samples. During the month of June 2008, very high flows occurred in Beaver Creek. It is likely that the high flows mobilized a large volume of sediment and probably resulted in considerable scouring of the sediment, particularly at this site. The reduced macro-benthos present in July may have been due, at least in part, to the high flows that occurred in June.

During a year with more moderate flows, the macro-benthos would likely show an increase in abundance and taxonomic richness throughout the growing season, while a year with drought conditions might have no flow in the riffles where the greatest diversity of benthic invertebrates is typically seen.

High pH, conductivity, and temperatures; and a high volume of fine sediment all may contribute to the depauperate invertebrate communities observed in Beaver Creek.

Table 5.4-24 Benthic Invertebrate Community Composition Metrics and Predicted Direction of Response to Perturbation

Category	Metric	Definition	Predicted response to increasing perturbation
Richness measures	Total taxa	Measures the overall variety of the macroinvertebrate assemblage	Decrease
	EPT taxa	Number of taxa in the insect orders Ephemeroptera (mayflies), Plecoptera (stoneflies), and Trichoptera (caddisflies)	Decrease
	Ephemeroptera taxa	Number of mayfly taxa (usually genus or species level)	Decrease
	Plecoptera taxa	Number of stonefly taxa (usually genus or species level)	Decrease
	Trichoptera taxa	Number of caddisfly taxa (usually genus or species level)	Decrease
Composition measures	% EPT	Percent composite of mayfly, stonefly, and caddisfly taxa	Decrease
	% Ephemeroptera	Percent of mayfly nymphs	Decrease
Tolerance/Intolerance measures	No. of Intolerant taxa	Taxa richness of those organisms considered to be sensitive to perturbation	Decrease
	% Tolerant organisms	Percent of macrobenthos considered to be tolerant of various types of perturbation	Increase
	% Dominant taxon	Measures the dominance of the single most abundant taxon. Can be calculated as dominant 2, 3, 4, or 5 taxa.	Increase
Feeding measures	% Filterers	Percent of the macrobenthos that filter fine organic particulate matter from the water column or sediment.	Variable
	% Grazers and Scrapers	Percent of the macrobenthos that scrape or graze upon periphyton	Decrease
Habitat measures	Number of clinger taxa	Number of taxa of clinging insects	Decrease
	% Clingers	Percent of insects having fixed retreats or adaptations for attachment to surfaces in flowing water.	Decrease

Fish

A total of 12 fish species were collected from the three sampling locations: BVC04–Beaver Creek upstream of the PAA; BVC01–Beaver Creek downstream of the PAA; and CHR05–Cheyenne River downstream of the confluence of Beaver Creek. The species, trophic category, and habitat notes are summarized in Table 5.4-27. The abundance (presented as catch per unit effort or fish per m of stream length), and average sizes of fish are shown in Table 5.4-28. Fish collection data forms are presented in Appendix 5.4--K.

Table 5.4-27 Fish Species and Trophic Categories

Species Code	Common Name	Latin Name	Trophic Category	Notes
SAS	Sand shiner	*Notropis stramineus*	Omnivore	
CRC	Creek chub	*Semotilus atromaculatus*	Primarily carnivorous omnivore	
PLM	Plains Minnow	*Hybognathus placitus*	Primarily herbiverous	Generally in slower water and side channels of turbid streams. Eats benthic algae & other plant material.
CAP	Common carp	*Cyprinus carpio*	Omnivore	Introduced species. Bottom feeder.
LND	Longnosed dace	*Rhynichthys cataractae*	Primarily carnivorous omnivore	Primarily in riffles
FHM	Fathead minnow	*Pimephales promelas*	Primarily herbiverous	Widely cultivated for bait, and extensively used in toxicological studies
RIC	River Carpsucker	*Carpoides carpio*	Bottom feeding omnivore	
SHR	Shorthead Redhorse Sucker	*Moxostoma macrolepidotum*	Bottom feeding carnivore	
CHC	Channel Catfish	*Ictalurus punctatus*	Bottom feeding omnivore	Species most likely to be eaten by humans.
PLT	**Plains topminnow**	***Fundulus sciadicus***	**Surface feeding carnivore**	
PLK	Plains Killifish	*Fundulus zebrinus*	Surface feeding carnivore	
GRS	Green sunfish	*Lepomis cyanellus*	Carnivore	Palatable but generally too small for human consumption

5.4.4.5.1.2.2.1 Locally Significant Fish Species

Recreational anglers fish Beaver Creek, although the Cheyenne River and Angostura Reservoir provide greater fishing opportunities in the area. Channel catfish is the species most likely to be caught and eaten from Beaver Creek.

Hampton (1998) calculated the relative weight index (Wr) for channel catfish in the Cheyenne River to assess the condition of this species in the Cheyenne River. Hampton (1998) reported a curvilinear relationship between weight and length (Ws=63.75 +5,780/L where Ws= standard weight, and L= total length). Comparing the weight/length ratio of channel catfish collected in this study to the standard weight (Ws) described above, the relative weight (Wr=100*W/Ws) can be used as an indicator of fish condition. Generally, relative weights greater than 100 indicate better than average condition and those less than 100 indicate poorer than average condition. The weight of the largest (290 mm) channel catfish collected from the Cheyenne River had a very high relative weight (Wr = 198) while the other catfish collected from the Cheyenne River had low relative weights (Wr = 51 and 52), and the one channel catfish collected from Beaver Creek (at BVC04) had a moderately low relative weight (Wr=79). Although the average Wr for the Cheyenne River channel catfish (100.8) indicates good agreement with Hampton's (1998) modeled relationship, the weight/length ratio of individual fish varied considerably. A larger sample size would be needed to draw any conclusions about the relative condition of fish from these sites.

Relative weights are shown in Table 5.4-29, below.

Table 5.4-29 Relative Weight Index for Channel Catfish Collected at Beaver Creek and Cheyenne River

Site	Date	Length	Weight	Standard Weight (Ws)	Relative Weight (Wr)
BVC04	Apr-08	215	72	90.6	79.4
CHR05	Jul-08	290	166	83.6	198.4
CHR05	Jul-08	186	50	94.8	52.7
CHR05	Jul-08	181	49	95.6	51.2
CHR05 Average					100.8

5.4.4.5.1.2.2.2 Threatened and Endangered Aquatic Species

No threatened or endangered aquatic species are known to inhabit Beaver Creek, particularly within 1.0 mile of the permit boundary.

The plains topminnow (*Fundulus sciadicus*) was captured in July at the downstream Beaver Creek site (BVC01). This species is tracked by SDNHP.

5.4.4.5.1.2.3 Radiological Testing

The channel catfish was the only species collected in April that contained detectable Uranium (0.05 mg/kg, and 3 X 10-5µCi/kg) (Table 5.4-30). Unfortunately this species was only collected from the downstream Beaver Creek site (BVC04) during that session. In July, channel catfish were only collected from the Cheyenne River site (CHR05). The channel catfish is the only species collected in the PAA that is typically caught for human consumption.

Uranium was detected in all of the fish collected in July 2008 due, in large part, to increased sample sizes (Table 5.4-30). As indicated, April samples showed little, if any, detectable Uranium, however, the detection limits were higher during that sampling effort due to matrix interference. Therefore, it is not possible to determine if there was an actual seasonal difference in fish tissue Uranium concentration. Uranium concentrations and uranium radioactivity were generally low and similar across sample sites when compared by species. Radioactivity from Polonium-210, Thorium-230, and Radium-226 was detectable, but low in most samples. Lead-210 was only detected in one specimen (plains killifish [Fundulus zebrinus]) collected in April at the downstream Beaver Creek site (BVC01). Although this measurement was relatively high (0.02 µCi +0.02 µCi), it should be noted that, due to matrix interference, the precision was limited on this sample. Lead-210 was not detected in any of the other samples.

[c]Due to matrix interference, the precision of this measurement was equal to the detected concentration (i.e. 0.02 µCi ± 0.02 µCi).

5.5 Climate Data

5.5.1 Introduction

The proposed project is located in an area in southwestern South Dakota that can be characterized as a semiarid or steppe climate. It lies adjacent to the southwestern extension of the Black Hills. The area experiences abundant sunshine, low relative humidity, and sustained winds which lead to high evaporative demand. There are also large diurnal and annual variations in temperature.

Precipitation in the PAA is generally light. Migratory storm systems that originate in the Pacific Ocean release a majority of their moisture over the Rocky or Cascade Mountains. Major precipitation events can occur when these systems regain moisture already present in the area or moisture advected from the Gulf of Mexico. Localized summer convective storms, caused by the Black Hills, can produce heavy precipitation events.

To complete the site-specific analysis, a weather station was installed in coordination with the South Dakota State Climatology office at approximately the center of the PAA in July 2007. This site collects temperature, humidity, solar radiation, wind speed/direction, barometric pressure, and precipitation at 1-minute, 5-minute, and hourly time steps. To determine whether this period of data collection (July 18, 2007, to July 17, 2008) was representative of long-term meteorological conditions, weather data from the nearest National Weather Service (NWS) site at Chadron, Nebraska, for the same period was compared to data collected at the site from years 1978–2007.

The data compiled from several sites (listed in Table 5.5-1 and shown in Figure 5.5-1) surrounding the PAA from the High Plains Regional Climate Center (HPRCC) and South Dakota State University (SDSU) was used to represent the long-term meteorological conditions of the Proposed Action region. All the sites were used to characterize regional trends of temperature and precipitation along with growing, heating, and cooling degree days. Only the SDSU sites had sufficient data available to analyze regional patterns of humidity, and only the Oral, South Dakota, site had adequate data to characterize wind speed/direction and evapotranspiration.

Data were analyzed at each site by time of day, month, and season of the year. The seasons for this analysis are defined as: winter (December, January, February), spring (March, April, May), summer (June, July, August), and fall (September, October, November).

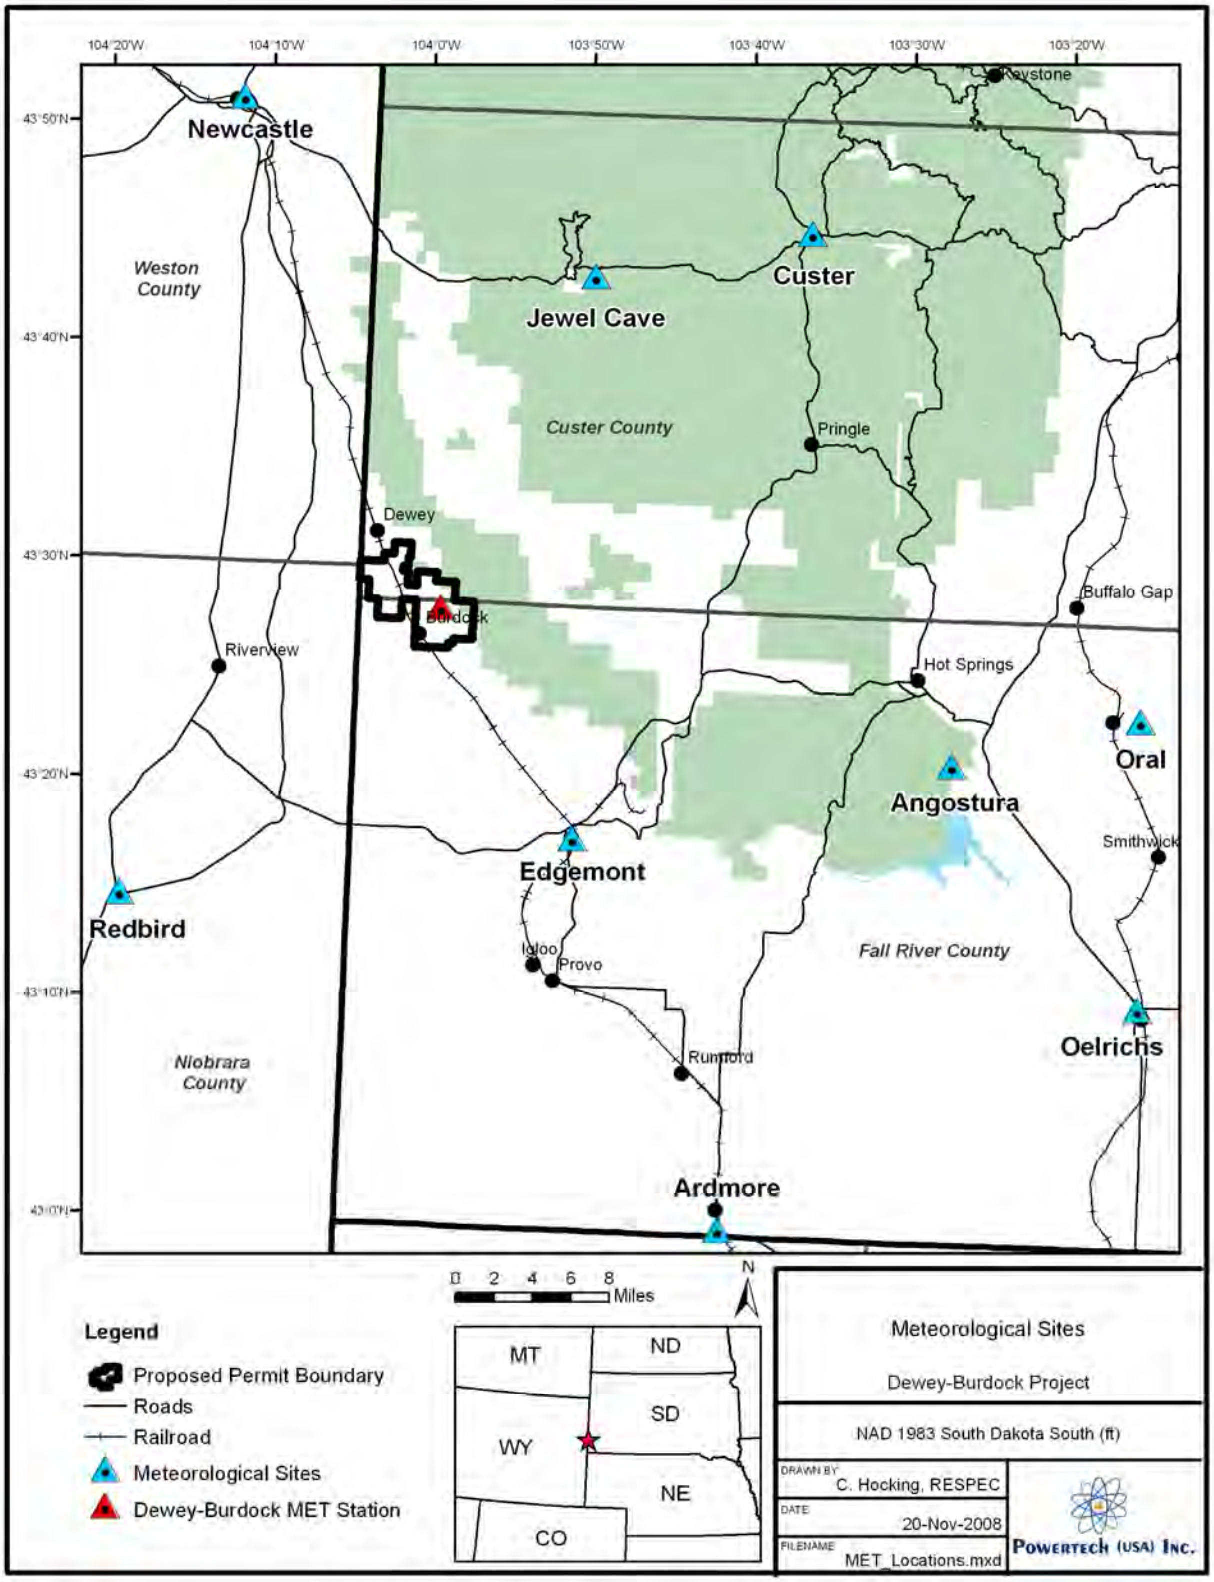

Figure 5.5-1 Meteorological Sites

5.5.2 Regional Overview

Meteorological data from the NWS site at Chadron, Nebraska, were collected from the HPRCC and analyzed to determine whether the past year's data (July 18, 2007, to July 17, 2008) was representative of long-term meteorological conditions (January 1, 1978, to July 17, 2008) in the area. The parameters analyzed were average daily temperature, wind speed, and precipitation.

The average daily temperature over the last (current) year was 47.8 degrees F, which is slightly cooler than the 30-year average (historic) daily temperature of 50.5 degrees F. Figure 5.5-2 displays a boxplot of the current and historic temperature data. The interquartile range for the current data is from 30.3 degrees F to 64.5 degrees F with a median value of 48.2 degrees F, compared to the historic data that has an interquartile range from 35.3 degrees F to 68.3 derees F and a median value of 50.5 degrees F. When looking at the data on a month-by-month basis, the mean value of the current data lies within one standard deviation of the mean value of the historic data (see Appendix 5.5-A).

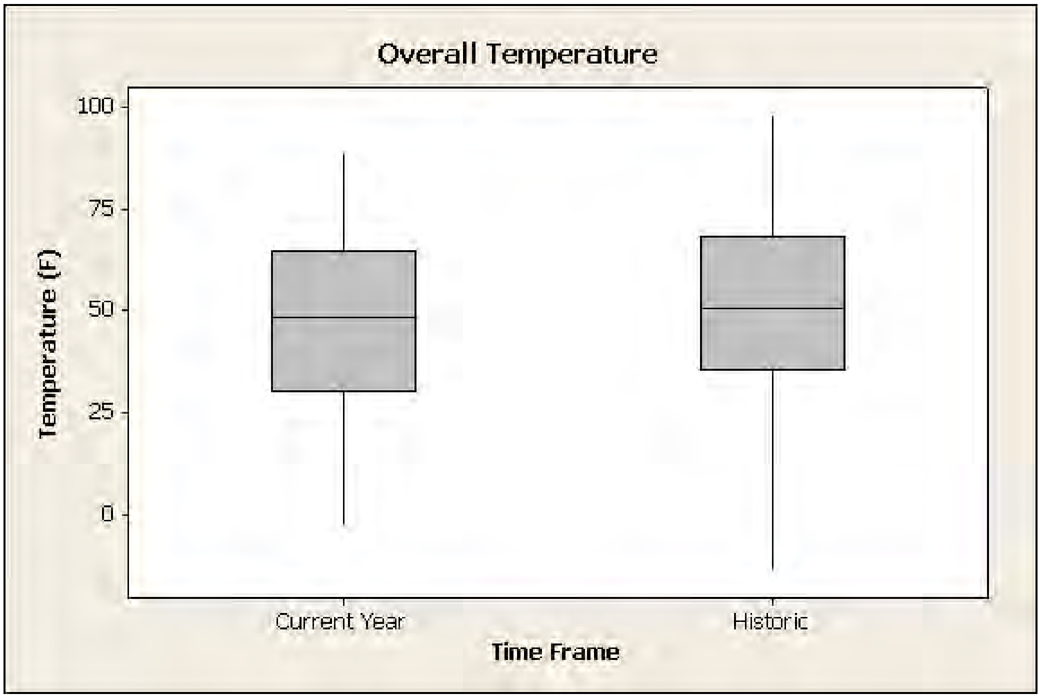

Figure 5.5-2 Temperature at Chadron, Nebraska, National Weather Service Site

The average daily wind speed over the current year was approximately 1 mph less than historically (9.8 to 10.8 mph). Figure 5.5-3 displays a boxplot of monthly wind speed for the current and historic data. The median value lies with the interquartile range for all months.

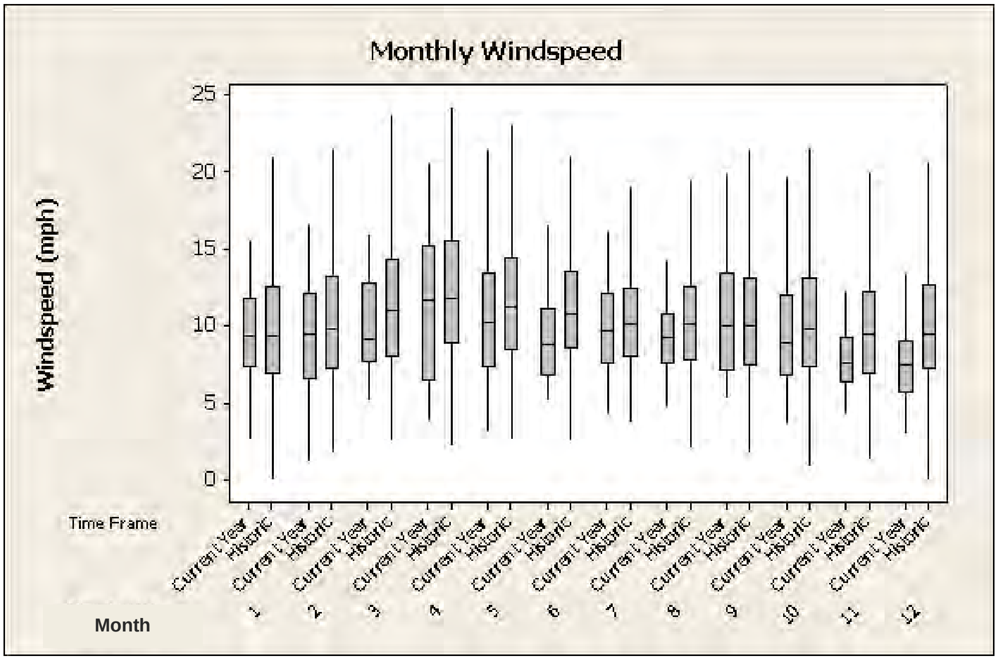

Figure 5.5-3 Monthly Wind Speed at Chadron, Nebraska, National Weather Service Site

The current year had well above the average amount of yearly precipitation. The current year had 32.8 inches of precipitation compared to the average yearly historic precipitation of 18.2 inches.

5.5.2.1 Temperature

The annual average temperature in this region is 46.7 degrees F. Figure 5.5-4 and Table 5.5-2 display the monthly, annual, and seasonal average temperatures. This region has some of its warmest days in the summer months with the hottest month being July (average temperature of 72.8 degrees F). The coldest month of the year is January, with an average temperature of 23.0 degrees F. The differences seen between sites can be attributed to elevation. Custer and Jewel Cave have the lowest average temperature primarily because these sites are nearly 1,000 feet higher in elevation than all other sites.

Figures 5.5-5 and 5.5-6 show the average maximum and minimum temperatures in the region. The average maximum temperature is 60.7 degrees F annually, while the annual average minimum temperature is 32.7 degrees F, as shown in Tables 5.5-3 and 5.5-4. The highest average maximum temperatures in the region usually fall during the month of July (88.3 degrees F). The lowest minimum temperatures can be found in January with a regional average of 10.4 degrees F.

Figures 5.5-7 and 5.5-8 display diurnal temperature variations by season for the Jewel Cave and Oral sites. These sites were used because they were the only sites that recorded hourly temperatures near the Proposed Action. As the figures show, there are large variations in diurnal temperature, especially during the summer months.

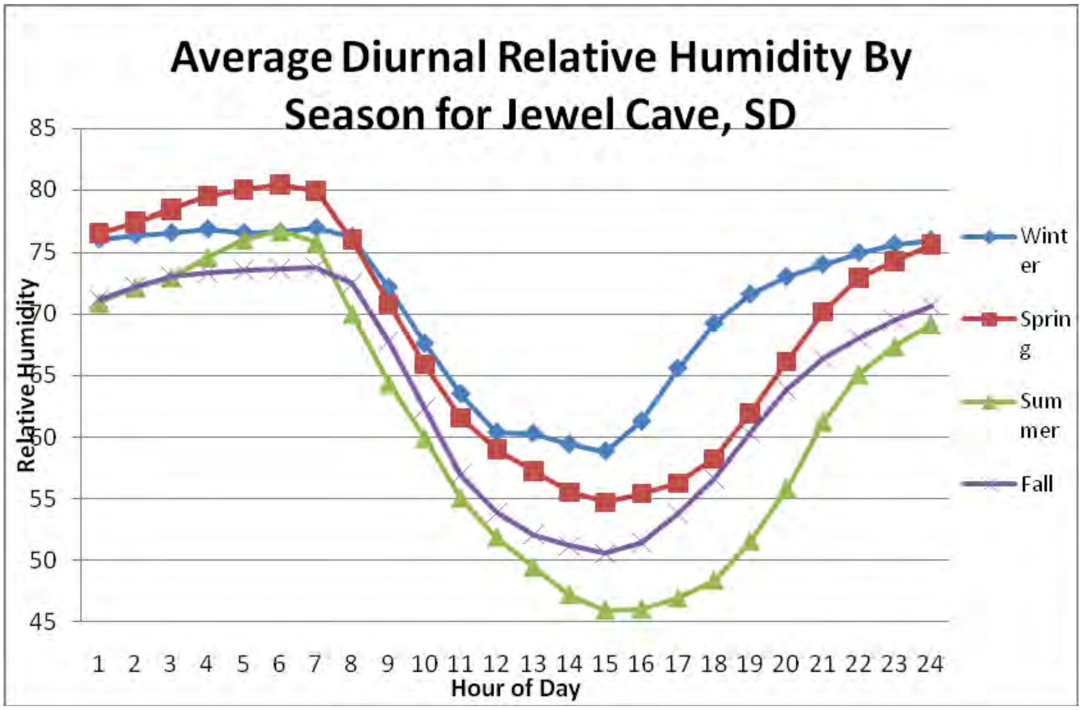
Figure 5.5-8 Oral, South Dakota, Seasonal Diurnal Temperature Variations

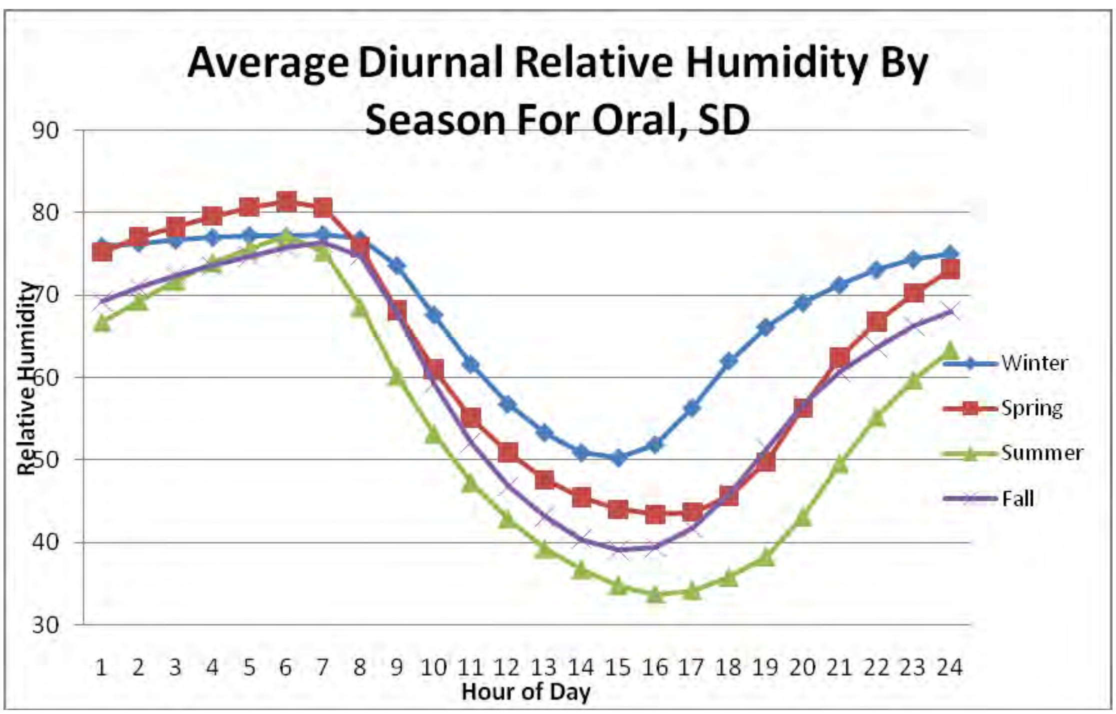
5.5.2.2 Relative Humidity

Relative humidity measures the fraction of moisture in the air to saturated moisture content at a certain temperature. This parameter was analyzed for both the Jewel Cave and Oral sites. Figures 5.5-9 and 5.5-10 display the relationship of relative humidity to the season and time of day for each site. The figures show that the summer has the lowest relative humidity, averaging 60 percent, while winter has the highest relative humidity, averaging 69 percent.



Source: South Dakota University, 2008

Figure 5.5-9 Average Diurnal Relative Humidity by Season for Jewel Cave, South Dakota



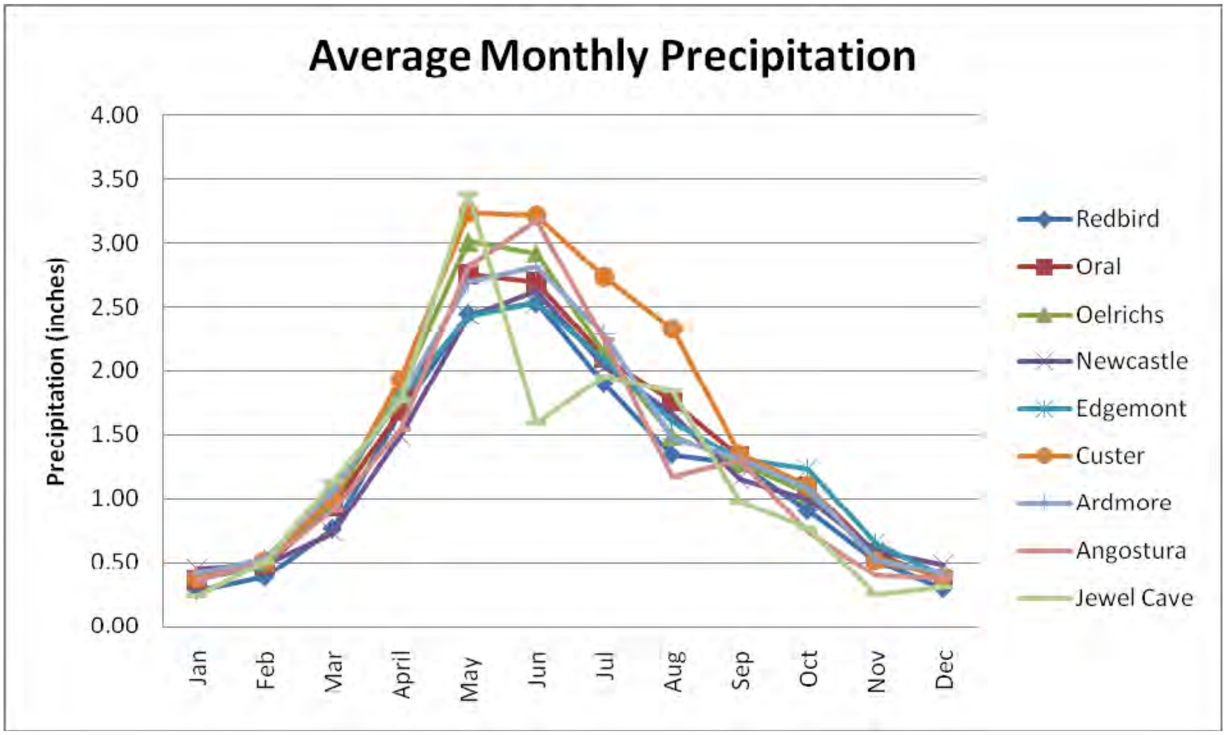
Source: South Dakota University, 2008

Figure 5.5-10 Average Diurnal Relative Humidity by Season for Oral, South Dakota

The relative humidity in this region peaks out in the morning at around 6:00 am with the minimum falling in the afternoon around 3:00 pm. The readings during the peak time average 77 percent at Jewel Cave and 78 percent at the Oral site. The readings with the lowest relative humidity during the day average 53 percent and 42 percent at Jewel Cave and Oral, respectively.

5.5.2.3 Precipitation

Figure 5.5-11 and Table 5.5-5 show that this area can be very dry at times with a regional annual average precipitation of 16.5 inches. Most of the precipitation accumulates during May, June, and July (48 percent of the annual). Typically, May is the wettest month of the year for this region with an average accumulation of 2.8 inches. Winter receives roughly 8 percent of the annual accumulated precipitation. January is the driest month of the year with an average accumulation of 0.36 inches of precipitation.



Source: High Plains Regional Climate Center, 2008; South Dakota University, 2008

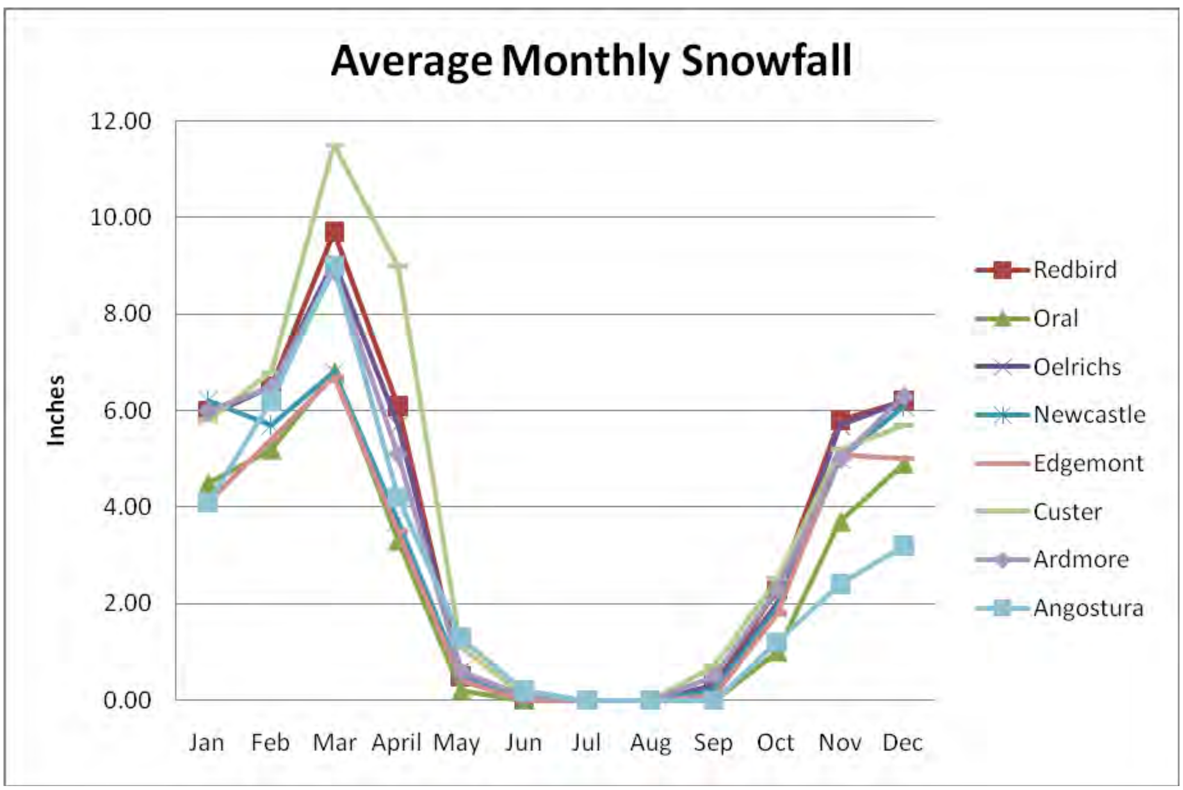
This region receives an average of 38 inches of snowfall each year. As shown in Figure 5.5-12, most snowfall accumulates during the month of March with a regional average of 8.5 inches. Custer receives the most annual snowfall (48 inches). This can be attributed to the higher elevation and the influence of the Black Hills that surround it (Figure 5.5-13).



Source: South Dakota University, 2008

Figure 5.5-13 Average Snowfall Accumulation throughout the Region

5.5.2.4 Wind Patterns

The Oral site was the only site in the region with representative data for wind speed and direction. The wind speed averaged 6.4 mph over the entire period of record with approximately 51 percent of the winds blowing from the southwest (Figure 5.5-14). Over 38 percent of the wind is between 1.2 and 4.6 mph (1 to 4 knots) with calm winds (less than 1.2 mph or 1 knot) occurring 2.5 percent of the time (Figure 5.5-15).

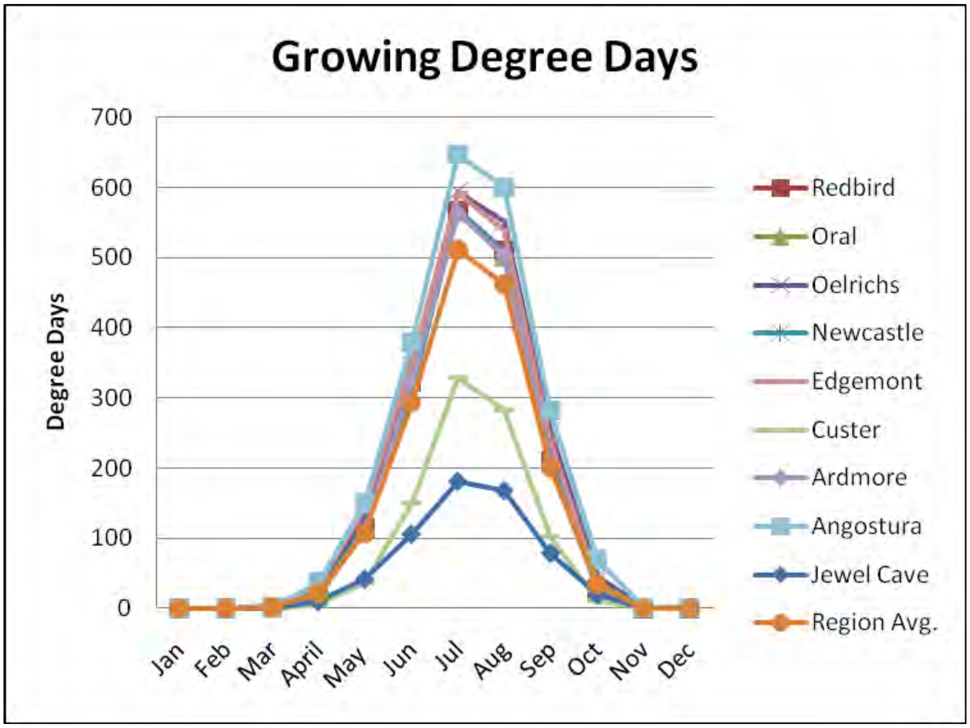
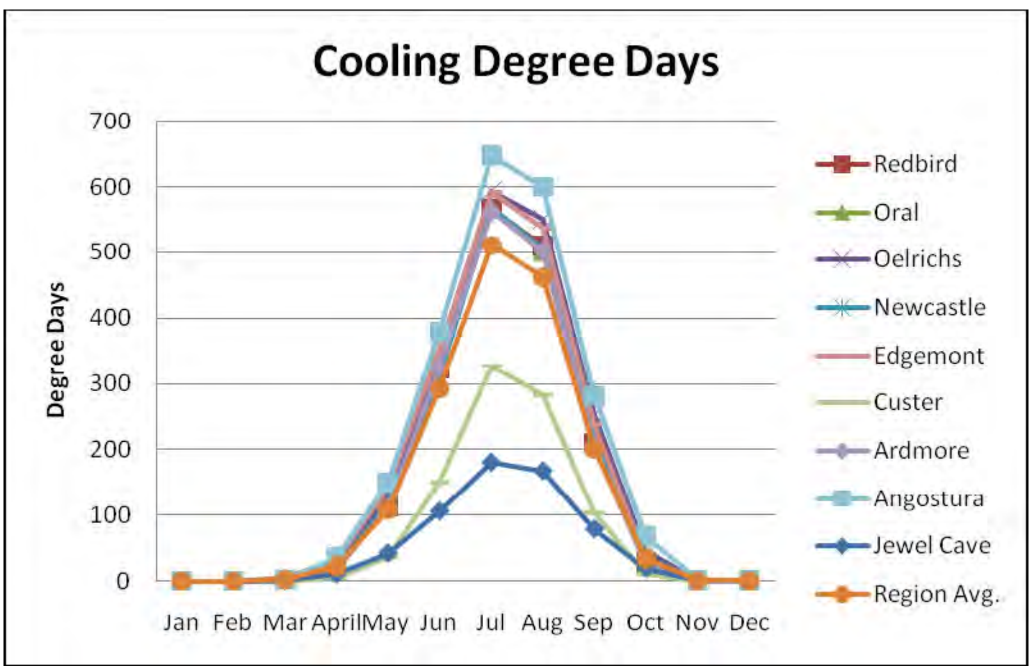
5.5.2.5 Cooling, Heating and Growing Degree Days

The graphs shown in Figures 5.5-16, 5.5-17, and 5.5-18 summarize the growing degree, cooling, and heating days for the nine meteorological sites in the area. The data show a similar pattern for all three parameters throughout the sites with the exception of the Jewel Cave and Custer sites, which is likely caused by the higher relative elevation of these two sites.



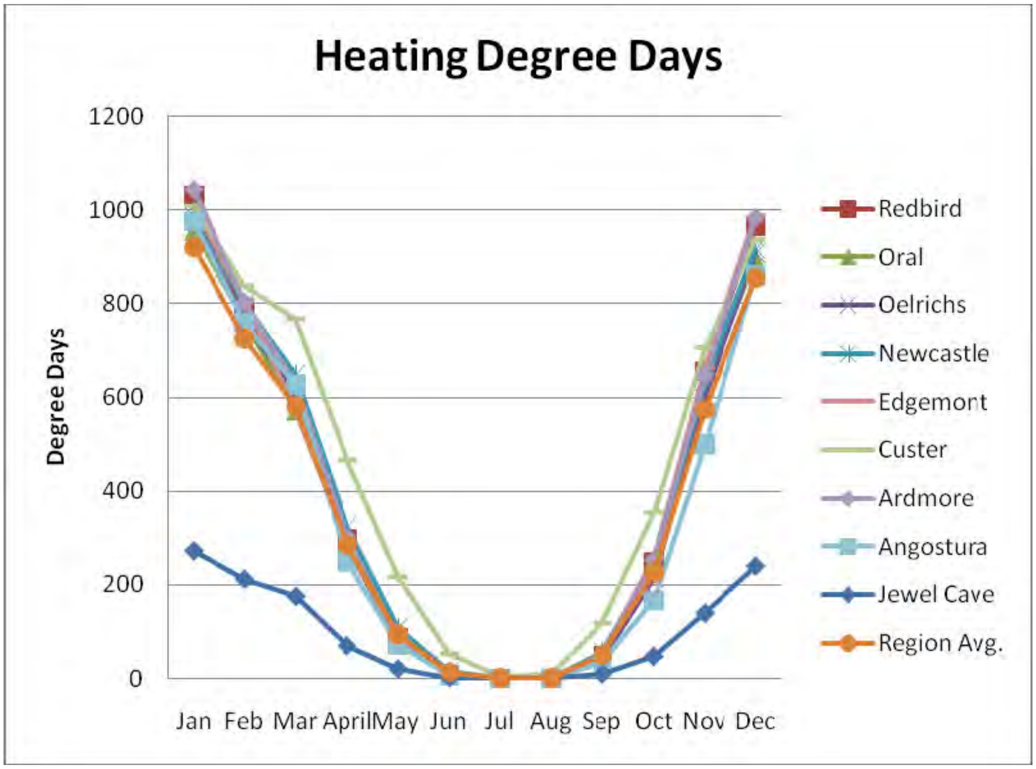
Source: High Plains Regional Climate Center, 2008; South Dakota University, 2008

Figure 5.5-16 Growing Degree Days for Regional Sites



Source: High Plains Regional Climate Center, 2008; South Dakota University, 2008

Figure 5.5-17 Cooling Degree Days for Regional Sites



Source: High Plains Regional Climate Center, 2008; South Dakota University, 2008

Figure 5.5-18 Heating Degree Days for Regional Sites

All degree days calculations used a base temperature of 55 degrees F. Heating and cooling degree days are included to show deviation of the average daily temperature from the chosen base temperature. The number of heating degree days is computed by taking the average of the high and low temperature occurring that day and subtracting it from the base temperature. The number of growing degree days and cooling degree days is computed in the opposite fashion where the base temperature is subtracted from the average of the high and low temperature for the day. Negative values are disregarded for both calculations.

5.5.2.6 Evapotranspiration

The American Society of Civil Engineers (ASCE) Standardized Reference Evapotranspiration Equation was used to calculate daily evapotranspiration (ET) using a tall reference crop coefficient. The weather parameters needed to calculate ET using this method are daily maximum and minimum temperature, maximum and minimum relative humidity, total solar radiation, and average wind speed. The Oral site was the only one in the region with all these weather parameters being sampled, and was, therefore, the site used for this analysis. The data were available from May 8, 2003, to July 20, 2008. Figure 5.5-19 displays a graph of the average accumulated ET for each month. Most ET occurs during the summer months of June, July, and August with an average monthly accumulation of 10.3 inches. During the winter months, low ET (2.8 inches) occurs because of low temperatures and low solar radiation.

5.5.3 Site Specific Analysis

The site-specific analysis was completed using data collected from a weather station installed in approximately the center of the proposed permit boundary. The station is located on a site that is representative of the area within the boundary. Twelve months of data from July 18, 2007, to July 17, 2008, are used for this analysis.

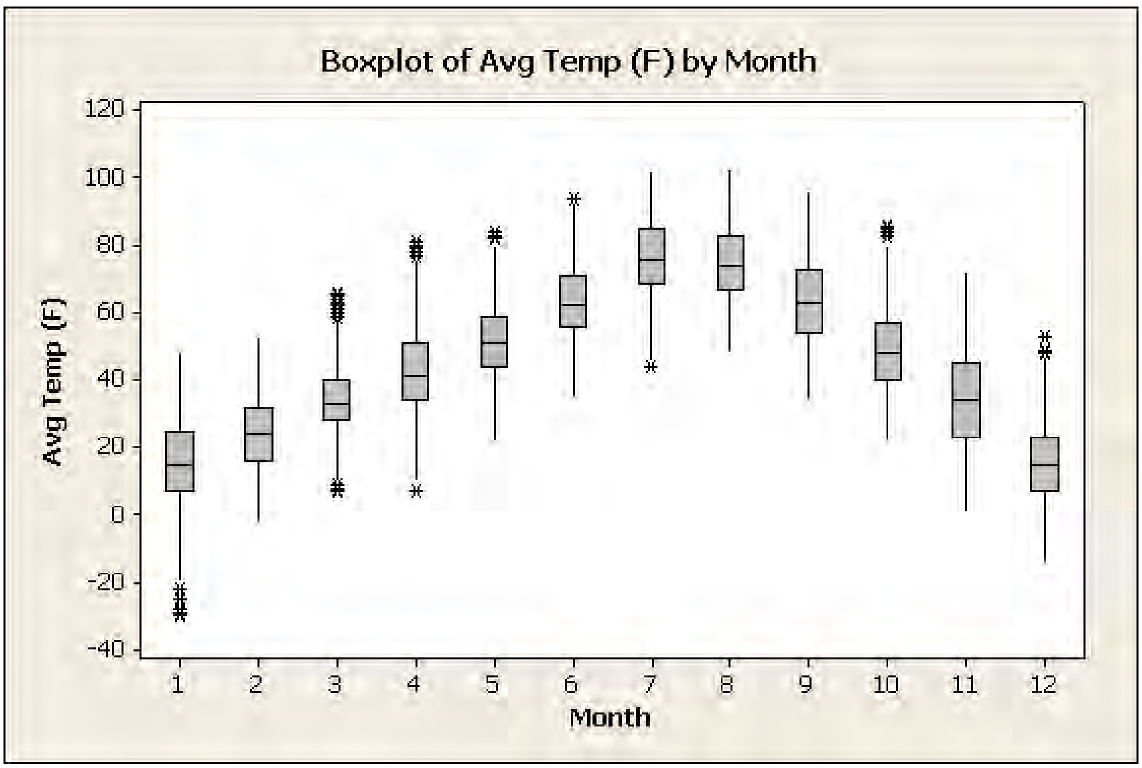
This site was installed in cooperation with the South Dakota State Climatology office according to the standards they use to install their Automatic Weather Data Network (AWDN) stations. The parameters being sampled at the site are air temperature, solar radiation, humidity, precipitation, and wind speed/direction at both 3- and 10-m heights (9.8 and 32.8 feet). Table 5.5-6 lists the model number and specifications of the sensors that were installed. The accuracy of all the sensors used is within the standards required by the NRC. All results of the statistical analysis, completed using **Minitab** software version 14.0 for the parameters analyzed, are included in Appendix 5.5-B.

Table 5.5-6 Specifications for Weather Instruments Installed to Perform Site-Specific Analysis

Measurement	Model	Manufacturer	Accuracy	Operating Temperature
Precipitation	VR6101	Vaisala	0.01 inch	–40°C to 60°C
Wind Direction	024A	Met-One	±5 degrees	–50°C to 70°C
Wind Speed	014A	Met-One	0.25 mph (0.11 m/s)	–50°C to 70°C
Temperature and RH	HMP45C	Vaisala	±2% for 10–90% RH; ±3% of 90–100% RH	–40°C to 60°C
Solar Radiation	L1200X	Lt-Cor	Absolute error in natural daylight is ±5% max; ±3% typical	–40°C to 65°C

5.5.3.1 Temperature

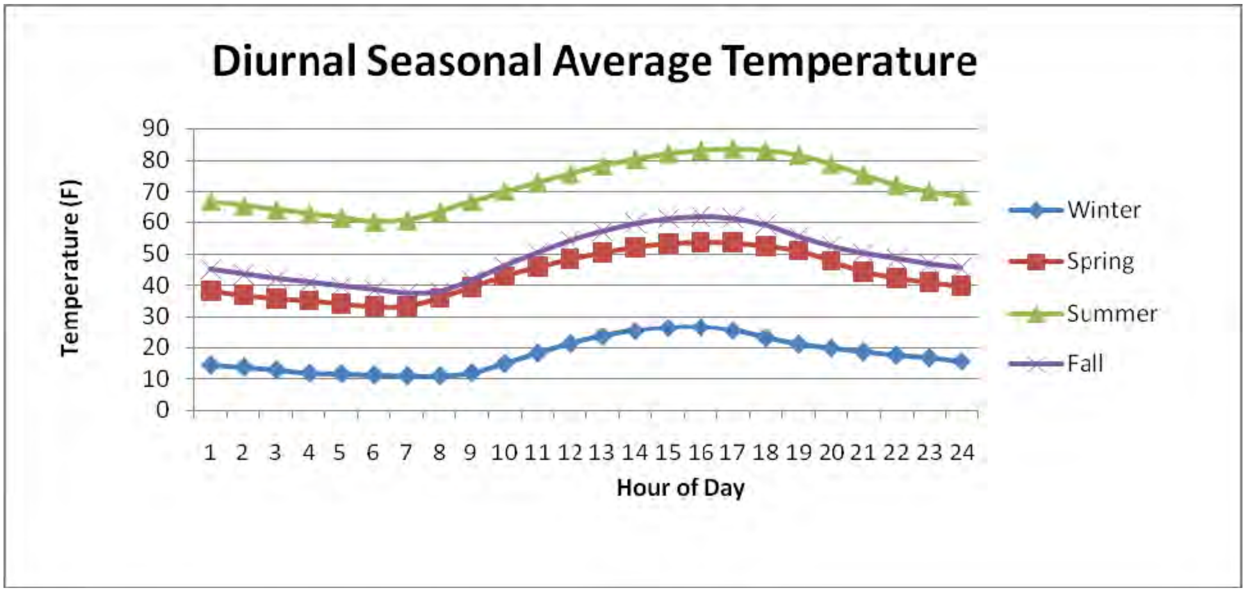
The average hourly temperature over the year for the site was 45.5 degrees F. A maximum temperature of 104 degrees F was reached on both July 21, 2007, and August 13, 2007, while the minimum temperature for the period of record was –28 degrees F on January 22, 2008. A boxplot of the average temperature by month is shown in Figure 5.5-20. July was the warmest month with a median temperature of 76 degrees F with a first quartile of 69 degrees F and a third quartile value of 85 degrees F. Conversely, December and January were the coolest months with a median temperature of 15 degrees F.



Source: South Dakota University, 2008

Figure 5.5-20 Average Temperature (degrees Fahrenheit) by Month from the PAA Meteorological Site

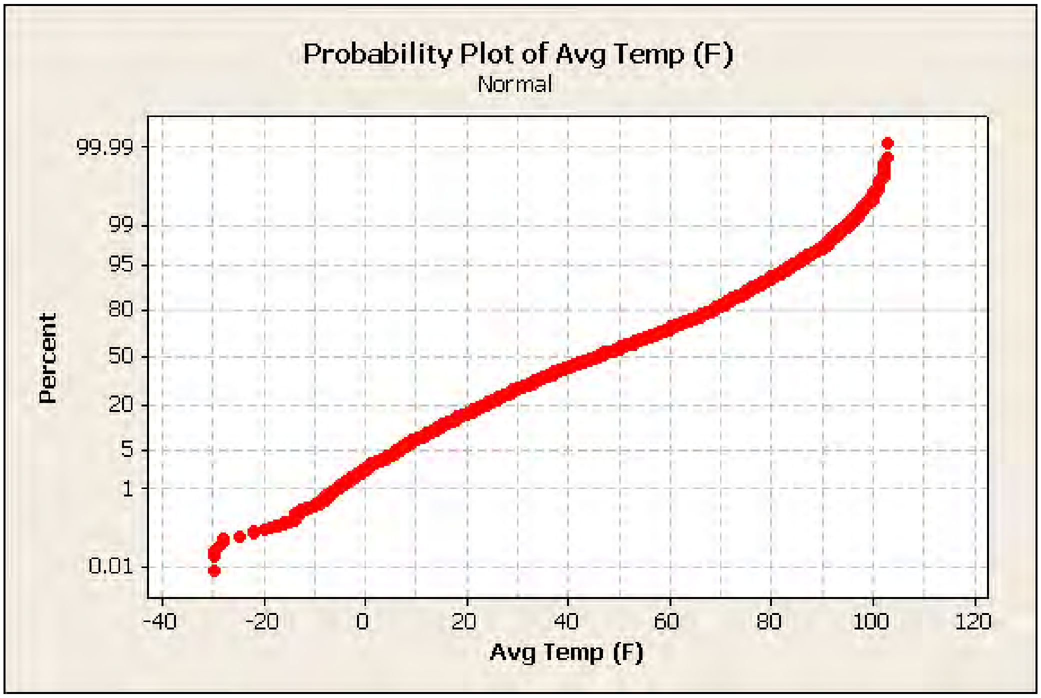
There were large variations in seasonal and diurnal temperature (Figure 5.5-21). In the summer season, average temperatures were as low as 60 degrees F at 6:00 am to 83.6 degrees F at 5:00 pm. In the winter season, temperatures varied from an average of 11 degrees F between 7:00 am and 8:00 am and rose to nearly 27 degrees F at 4:00 pm. The diurnal variations are the result of the lack of relative humidity in the atmosphere at the site, which causes the earth's surface to rapidly absorb and release the energy supplied by the sun.



Source: South Dakota University, 2008

Figure 5.5-21 Diurnal Average Temperature for the PAA Meteorological Site by Season

Figure 5.5-22 shows a probability plot of average hourly temperature for the year. Temperatures above or below 46 degrees F were expected at the site 50 percent of the time, and temperatures dipped below the freezing mark of 32 degrees F 31 percent of the time.



Source: South Dakota University, 2008

Figure 5.5-22 Probability Plot of Average Temperature from the PAA Meteorological Site

5.5.3.2 Wind Patterns

Wind speed and direction was measured in the field using Met-One 014A and 024A model sensors. Statistical analysis and visualization of wind data were performed using WRPLOT View Version 5.3 distributed by Lakes Environmental. All data analysis outputs are included in Appendix 5.5-C. The average wind speed over the period of record was approximately 5 mph, while calm winds occurred only 1.8 percent of the time.

As shown in Table 5.5-7, a majority of the winds (51 percent) come from the southeast and approximately 55 percent of all winds were less than 4.6 mph. December had the least amount of wind with 7.66 percent of the total winds being classified as calm and having an average wind speed of 2.8 mph. In contrast, May was the windiest month with only 0.41 percent of calm winds and an average wind speed of 6.9 mph. Southeasterly winds were prevalent in the winter months (38 percent of total shown in Figure 5.5-23) as well as the summer months (56 percent of total shown in Figure 5.5-24).

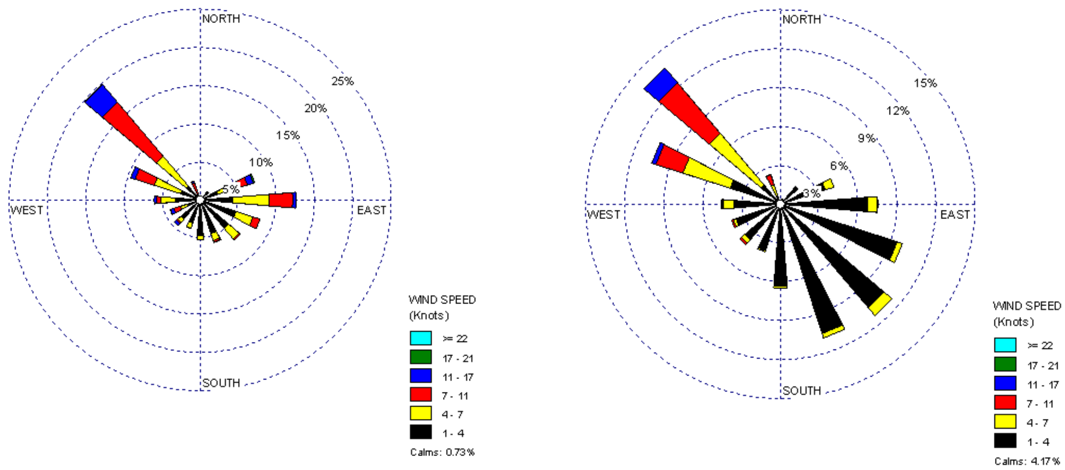

Figure 5.5-23 Winter and Spring Wind Roses

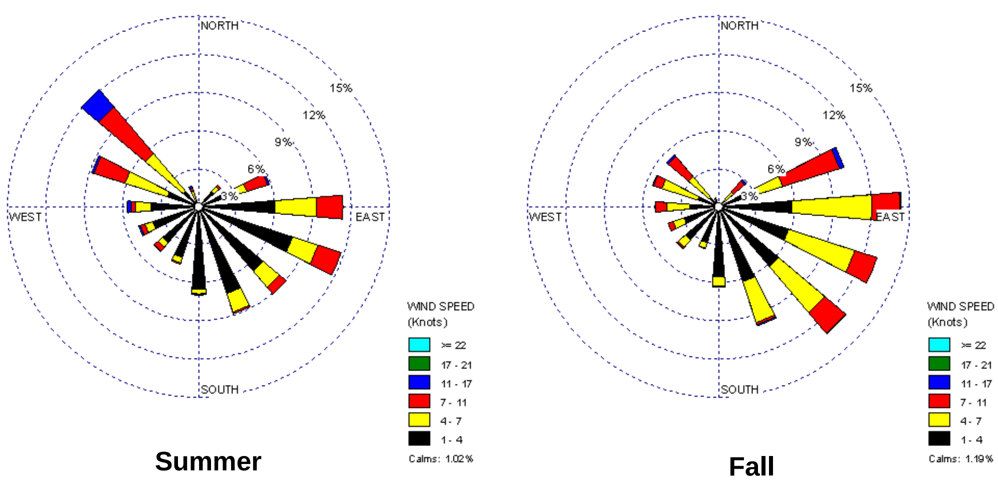

Figure 5.5-24 Summer and Fall Wind Roses

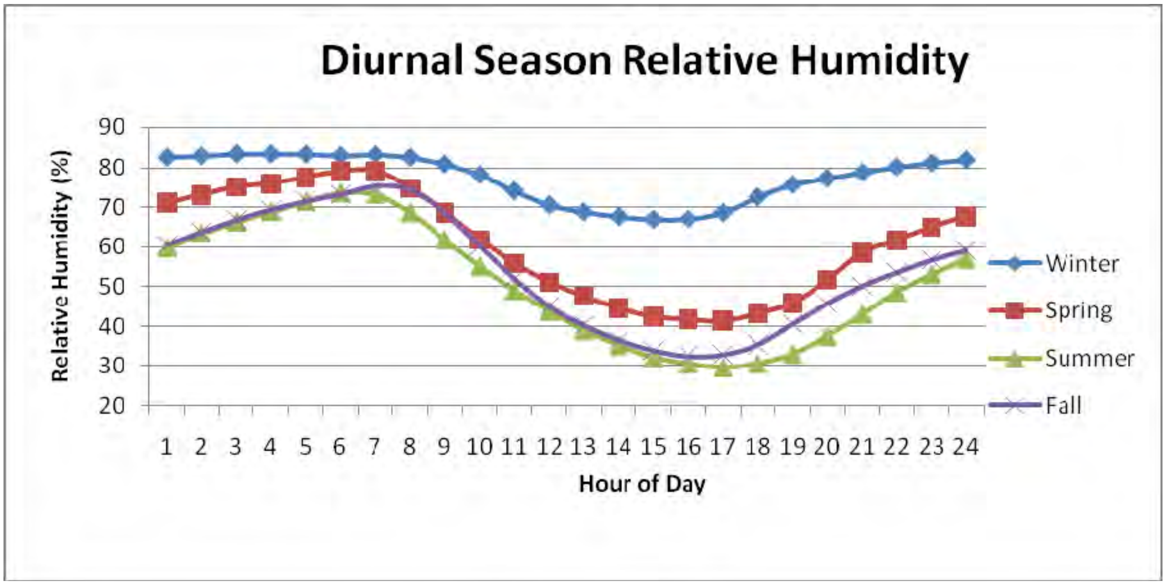
5.5.3.3 Relative Humidity

As mentioned in previous sections, the relative humidity at the site is low. Mean values range from a low of 51 percent in the summer months compared to a high of 77 percent in the winter months. Relative humidity values varied greatly throughout the day, especially in the summer and spring months. On average, during the spring, summer, and fall months, relative humidity reached its maximum from 5:00 am to 7:00 am and then declined steadily until 4:00 pm to 5:00 pm when it began its evening ascent (Figure 5.5-25). During the winter months, the diurnal relative humidity range was much less because of less intense and shorter duration solar radiation.

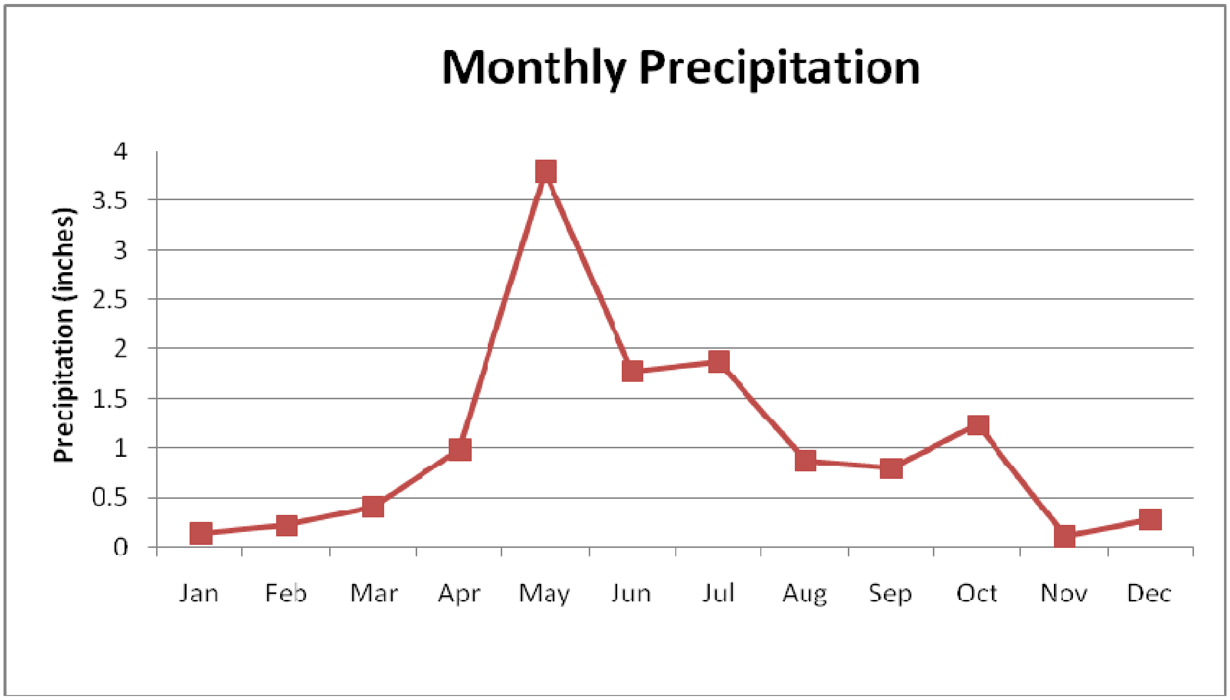


Source: South Dakota University, 2008

Figure 5.5-25 Diurnal Relative Humidity by Season from Project Meteorological Site

5.5.3.4 Precipitation

Data for this site were collected using a Vaisala VRG 101 all-weather precipitation gauge. The region received 12.42 inches of precipitation during the year of monitoring. Figure 5.5-26 displays the precipitation totals by month. The largest monthly precipitation total occurred in May (3.8 inches) and the least occurred in November (0.10 inch). The greatest daily precipitation total (1.29 inches) occurred on May 23, 2008. Also on May 23, 2008, the area received 0.71 inch of precipitation between the hours of 8 p.m. and 9 p.m., which was the most intense event of the sampled year.



Source: South Dakota University, 2008

Figure 5.5-26 Monthly Precipitation from the PAA Meteorological Site

5.5.3.5 Potential Evapotranspiration

The potential ET data were taken from July 18, 2007, to July 14, 2008. The ASCE Standardized Reference Evapotranspiration Equation for a tall reference crop was used to estimate daily ET. The weather parameters needed to estimate ET using this method are daily, maximum and minimum temperature, maximum and minimum relative humidity, total solar radiation, and average wind speed. Most ET occurs during the months of July, August, and September with an average monthly accumulation of 10.3 inches (Figure 5.5-27) because of the high temperatures and unstable weather. During the winter low, ET occurs because of low temperatures and low solar radiation. The average ET during the winter months is 1.5 inches.

Figure 5.5-27 Estimated Evapotranspiration Calculated Using Weather Data Collected at the PAA Meteorological Site

5.6 Mining Chemicals and Wastes Management

5.6.1 Chemical Storage Facilities

The ISL process requires chemical storage and feeding systems to store and use chemicals at various stages in the extraction, processing, and waste treatment processes. Chemical storage and feeding systems will include sulfuric and/or hydrochloric acid, sodium hydroxide, hydrogen peroxide, carbon dioxide, oxygen, sodium chloride, sodium carbonate, barium chloride, and propane. Each chemical storage and feeding system will be designed to safely store and accurately deliver process chemicals to their intended delivery point in the process. Design criteria for chemical storage and feeding systems include applicable sections of the international building code, international fire code, OSHA regulations, Resource Conservation and Recovery Act (RCRA) regulations, and Homeland Security regulations.

5.6.1.1 Sodium Chloride Storage

Sodium chloride will be used to make up fresh eluant and will be stored in tanks as a saturated solution (approximately 26 percent by weight) in equilibrium with a bed of crystals in each storage tank. Dry sodium chloride will be delivered by truck and will be blown into the storage tanks using air pressure.

5.6.1.2 Sodium Carbonate Storage

Sodium carbonate will be used to make up fresh eluant and will be stored in tanks as a saturated solution in equilibrium with a bed of crystals in the storage tank. Sodium carbonate solution must be kept above 140 °F to prevent precipitation in the tank and piping. This will be accomplished by heating the water added to the tank, and continuously circulating liquid from the tank through a heat exchanger. An electric heater will be used to heat a thermal fluid to heat the exchanger. Dry sodium carbonate will be delivered by truck and will be blown into the storage tanks using air pressure.

5.6.1.3 Acid Storage and Feeding System

The acid storage and feeding system will include a storage tank and delivery pump. The storage tank will be located outside of the CPP building in a lined concrete secondary containment basin designed to contain 110 percent of tank volume plus a 25 year, 24 hour storm event. This secondary containment basin will be separate from the containment basins for other chemical systems. The acid feed pump will be located inside the building, directly adjacent to the storage tank.

5.6.1.4 Sodium Hydroxide Storage and Feeding System

The sodium hydroxide system will include a storage tank and delivery pump. The storage tank will be located outside of the CPP building in a concrete secondary containment basin designed to contain 110 percent of tank volume plus a 25-year, 24-hour storm event. This secondary containment basin will be separate from the containment basins for other chemical systems. The sodium hydroxide feed pump will be located inside the building, directly adjacent to the storage tank. Sodium hydroxide will be purchased as aqueous caustic soda, and will be pumped directly into the storage tank from the supplier's tanker trucks.

5.6.1.5 Hydrogen Peroxide Storage and Feeding System

The hydrogen peroxide system will include a storage tank and delivery pump. The storage tank will be located outside of the CPP building in a concrete secondary containment basin designed to contain 110 percent of tank volume plus a 25-year, 24-hour storm event. This secondary containment basin will be separate from the containment basins for other chemical systems. The hydrogen peroxide feed pump will be located inside the building, directly adjacent to the storage tank.

5.6.1.6 Oxygen Storage and Feeding System

Oxygen is typically stored near the central plant or within well field areas, where it is centrally located for addition to the injection stream in each header house. Since oxygen readily supports combustion, fire and explosion are the principal hazards that must be controlled. The oxygen storage facility will be located a safe distance from the CPP and other chemical storage areas for isolation. The storage facility will be designed to meet industry standards in NFPA-503.

5.6.1.7 Carbon Dioxide Storage and Feeding System

The carbon dioxide storage and feeding system will be used to dissolve carbon dioxide into the pregnant lixiviant to improve recovery of uranium in the ion exchange vessel. This system will be a vendor supplied packaged system including cryogenic tank, vaporizer, pressure gauges, and pressure relief devices.

5.6.1.8 Barium Chloride Storage and Feeding System

The barium chloride storage and feeding system includes a storage tank, agitator, and chemical metering pump. This system will be designed to dissolve solid barium chloride in water to make up the solution for feeding into the low total dissolved solids (TDS) wastewater for radium precipitation. This system will be located in a metal building located adjacent to the low TDS wastewater pond.

5.6.1.9 Non-Process Related Chemicals

Non-process related chemicals that will be stored at the project CPP include petroleum (gasoline, diesel) and propane. Due to the flammable and/or combustible properties of these materials, all bulk quantities will be stored outside of process areas at the facility. All gasoline and diesel storage tanks are located above ground and within secondary containment structures to meet EPA requirements. Non-regulated AEA liquid wastes such as used oil, hydraulic fluid, cleaners, solvents and degreasers will be recycled or disposed offsite at a permitted hazardous waste facility or other EPA approved disposal methods.

5.6.2 Historical Mine Wastes

Existing mine waste overburden remains over portions of the eastern side of the known mineralization. Powertech does not plan to conduct operations through the mine waste at this time due to the potential of increased liability associated with the potential for reclamation on waste having no relationship to ISL production. In the future, if liability is not an issue and/or reclamation is undertaken on these waste piles, Powertech will revisit the issue of known mineralization that is currently deemed inadvisable to exploit. In any event the same control and protection standards will be used for in situ mining should these areas be developed in the future.

5.6.3 Solid Waste Management

Solid wastes such as pond sludge; soils contaminated by spills or leaks; spills of loaded or spent IX resin; filter sand or other process media; and parts, equipment, debris (e.g., pipe fittings and hardware) and personal protective equipment (PPE) that cannot be decontaminated for unrestricted release are considered Atomic Energy Act (AEA) regulated wastes and will be disposed of at a licensed 11e(2) disposal facility. Non-regulated AEA solid wastes such as office trash and spent equipment parts not associated with uranium production will be disposed at an off-site municipal Subtitle D facility. Domestic sewage will be disposed in an on-site septic system and leachfield or other disposal methods permitted under State of South Dakota regulations.

Non-radioactive solid waste will be managed in accordance with existing regulations and disposed of in a landfill that has been permitted under subtitle D of RCRA.

5.6.4 Liquid Waste Management

There are several disposal options for the liquid waste generated during the production and restoration process including brine concentrators, discharge to surface waters, evaporation ponds, deep well injection and land application. The National Pollution Discharge Elimination System (NPDES) permitting process allows for the discharge of treated liquid effluents to surface waters that meet state and federal water quality standards, but surface discharge has been rejected because it is a poor use of water resources in a water sensitive region. The sole use of evaporation ponds was rejected because of the large surface impoundment area that would be required to evaporate the daily bleed water and the severe winters that would freeze the ponds for several months out of the year, thereby decreasing the evaporation rates. The use of the evaporation process in conjunction with a Class V deep disposal well or land application to handle the CPP waste, is considered to be the best alternatives to dispose of these types of liquid waste.

5.6.4.1 Types of Liquid Wastes

Wastewater from the Proposed Action will consist primarily of spent CPP elution brines, production well field bleed, and restoration flows; these wastewaters will be disposed of by injection into a Class V injection well(s), or by treatment and subsequent land application. Specific liquid waste sources will include:

- Wastewaters from decontamination showers, sinks, and washing machines located in the restricted area
- Production bleed
- Spent eluant brines
- Spilled process liquids

- Wastewater from groundwater restoration
- Decontamination/decommissioning solutions from surface facilities

As part of the wastewater management plan, there may be periodic releases of water from storage ponds for the beneficial use of crop irrigation.

5.6.4.2 Out of State Disposal

Powertech originally proposed that one method of liquid waste disposal would be to pipeline liquid waste from Dewey-Burdock to a deep well injection site(s) located in Wyoming. A second potential method of liquid waste disposal was to truck concentrated liquid waste to licensed disposal wells in Wyoming or Nebraska. In Powertech's discussion with both states, it has been determined that neither state is willing to accept liquid waste from an adjacent state. Therefore, the proposed options described in Section 4.2.2.2 of the Technical Report are not viable at this time and are hereby withdrawn.

5.6.5 Deep Disposal Well Option

Powertech has determined that Class I (Hazardous Waste) deep injection wells are prohibited within South Dakota, and in fact, the probability of discovering a horizon that has no possibility of a USDW horizon beneath the injections zone is remote. Therefore, Powertech intends to propose to the U.S. EPA that the company permit Class V (Non Hazardous) deep disposal wells within the project area. The proposed locations of the wells are shown on Exhibit 1.1-2 Deep Disposal Well Option_. Regional geology and measurements of water character value within the Minnelusa horizon of Permian Age shows that the horizon has sufficient permeability and sufficiently low water quality that deep well injection would be viable for disposal of process liquid waste with removal of hazardous constituents. The requisite ponds for extraction of radium are shown on Exhibit 1.1-2 Deep Disposal Well Option as Radium Settling Ponds.

The deep well(s) identified by Powertech (USA) will isolate liquid waste generated during the production and restoration processes from any underground source of drinking water (USDW).

5.6.5.1 Disposal Well Design

Cross Sections show the section that will be proposed for permitting. It is clear from these cross sections that the depth and character of the horizon is of sufficient thickness to support the application for a Class V permit. Powertech proposes that prior to beginning of injection operations, that the company will apply for and receive the appropriate permits to allow disposal of liquid wastes in these wells. In addition, prior to operation, the drilled and completed Class V wells will be thoroughly tested with results submitted to all appropriate agencies for approval of injection of non-hazardous waste water with appropriate controls.

Exhibit 1.1-1 show the proposed location of the Radium Settling Ponds that would be used prior to land application. In addition to the Radium Settling Ponds, wastewater holding ponds would be necessary for land application due to the lower evaporation rate in winter time. Powertech proposes the use of irrigation pivots to apply non hazardous waste water that meets the effluent discharge standards to the surface in order to grow an agricultural crop. This method was used regularly at Hobson, Mount Lucas and Highlands with no deleterious effect on the environment.

5.6.5.2 Pond Design

It is proposed that depending on the method of disposal ultimately selected, that all final data and design of as-built ponds will be submitted to the NRC and all appropriate agencies. The complete package will include design under the strictest engineering standards and will be designed and signed off by certified professional engineers.

Pond and water application designs for the land application option and pond designs for the deep well disposal option are presented in the Pond Design Report provided in Appendix 4.3-A. These designs have been completed following NRC Regulatory Guide 3.11-Rev. 1, NUREG 1569, 10 CFR Part 40, Appendix A, Criterion 5 and State of South Dakota Administrative Rule 74:29:11:23. A summary of the designs for both liquid waste disposal options is provided below.

5.6.5.2.1 Land Application Ponds

The land application option includes six categories of ponds:

- Radium settling ponds containing bleed and restoration water and are used to settle radium out of solution.
- Outlet ponds used to intercept treated water from the radium settling ponds and to store storm water falling on the radium settling ponds.
- Storage ponds used to store treated water during the non-irrigation season.
- A central plant pond containing brine produced at the Burdock Plant site.
- A spare pond used for emergency containment should the radium settling or central plant ponds fail.
- A spare storage pond used for emergency containment should any of the storage ponds fail or portions of the land application system become temporarily inoperable.

The design of the land application ponds includes the following:

- Two radium settling ponds, one each at the Dewey and Burdock, having a storage capacity of 39.4 acre-ft each.
- Two outlet ponds, one each at the Dewey and Burdock sites having a storage capacity of 4.9 acre-ft each.
- Two sets of storage ponds:
  - A system of 4 ponds constructed at the Dewey Site each having a storage capacity of 63.8 acre-ft.
  - A system of 4 ponds constructed at the Burdock Site each having a capacity of 63.8 acre-ft.
- One spare storage pond at the Dewey Site having a storage capacity of 63.8 acre-ft.
- A central plant pond at the Burdock Site having a capacity of 36.2 acre-ft.
- A spare pond at the Burdock Site having a capacity of 39.4 acre-ft.

5.6.5.2.2 Deep Well Disposal Ponds

The deep well disposal option includes four categories of ponds:

- Radium settling ponds, containing bleed water and restoration water and used to settle radium out of solution.
- Outlet ponds used to intercept treated water from the radium settling ponds and to store storm water falling on the radium settling ponds.
- A surge pond, containing water that has been treated and which is to be pumped to the disposal wells.
- A spare pond used for emergency containment should a liner on any of the ponds fail.
- A central plant pond containing brine produced at the Burdock Plant Site.

The design of the deep disposal well ponds includes the following:

- Two radium settling ponds, one each at the Dewey and Burdock sites having a storage capacity of 15.9 acre-ft each.
- Two outlet ponds, one each at the Dewey and Burdock sites having a storage capacity of 5.1 acre-ft each.
- Two surge ponds, one each at the Dewey and Burdock sites having a storage capacity of 8.4 acre-ft each.
- A central plant pond at the Burdock site having a capacity of 15.9 acre-ft.
- A spare pond at the Dewey Site having a capacity of 15.9 acre-ft.

All ponds have been designed to store water reporting to them while maintaining 3 feet of freeboard. The geometry and storage characteristics of the radium settling ponds have also been checked to verify that they will allow the efficient removal of radium from solution.

The radium settling, spare and central plant ponds will be provided with the following lining system:

- An 80-mil-HDPE primary liner
- A 60-mil-HDPE secondary liner
- A 1-ft-thick clay liner below the secondary liner
- A geonet drainage layer sandwiched between the primary and secondary HDPE liners
- A leak detection sump and access port system

All other ponds will contain treated water that is either to be used for land application or deep well disposal. These ponds will include a single 80-mil-HDPE liner underlain by a 1-ft-thick clay liner.

The results of the stability analyses calculated for the embankments using three different methods of analysis; Bishop Method, Janbu Method and Morgenstern-Price Method indicate that the slopes are stable under both static and MCE seismic loading conditions.

5.6.6 Groundwater Restoration, Decommissioning and Site Reclamation

Groundwater restoration will be implemented as part of routine ISL operations so that restoration can be performed after a well field is depleted of uranium but concurrently with the development of subsequent well fields for uranium production. The goal of the groundwater restoration program will be to return water quality within the exempted aquifer consistent with pre-operational baseline quality conditions or other NRC approved standard in accordance with NRC's application of 10 CFR Part 40 Appendix A Criterion 5(b)(5) to ISL operations. It is anticipated that a combination of phases and technologies will be utilized to restore groundwater. These restoration phases and technologies are described in Section 4.2.

The decommissioning of well fields will commence following regulatory agency acceptance of the groundwater restoration program. The well field decommissioning will include well plugging and abandonment and the removal of well field piping, instrumentation and other support structures. At the time the CPP is decommissioned, all process equipment, buildings and ancillary equipment will be decontaminated for unrestricted release or disposed at an NRC approved facility.

During site decommissioning and decontamination (D&D), areas that exceed NRC soil concentration limits will be cleaned and then surveyed for compliance with applicable standards. Surface topography and drainage patterns that have been disturbed during operations (including the surface impoundment) will be re-established and will be revegetated with native species.

5.6.7 Surety Arrangements

In accordance with 10 CFR Part 40, Appendix A, Criterion 9, related NRC guidance, and existing Commission administrative case law, ISL operators are required to submit detailed financial assurance cost estimates to NRC Staff for approval prior to the issuance of a license for ISL operations. Pursuant to these requirements, an ISL operator must submit a detailed, line-item cost estimate (breakdown) of the activities and their associated costs that are necessary to complete site-specific D&D, including groundwater restoration, and to release the project site for unrestricted use. As part of this license application, Powertech (USA) has prepared a detailed, line-item financial assurance cost estimate for the Proposed Action, including the mandatory minimum fifteen (15) percent contingency over and above the costs associated with site D&D. This financial assurance cost estimate is provided in Section 6.6.

However, while NRC regulations and requirements require NRC approval of such cost estimates, such regulations and requirements do not require identification of Powertech (USA)'s specific financial assurance mechanism (e.g., surety bond, letter of credit, etc.) that will be used to provide such financial assurance nor do they require posting of the required funding until the operator is prepared to commence licensed operations at its project site. As a result, Powertech (USA) submits that it will identify and supply a financial assurance mechanism for the amount of funding approved by NRC in accordance with 10 CFR Part 40, Appendix A, Criterion 9 and NUREG-1757, Volume 3 prior to the commencement of licensed operations.

In addition, Powertech (USA) recognizes that NRC's application of Criterion 9 to ISL operations requires annual financial assurance updates to account for potential changes in the approved financial assurance cost estimate such as inflation, increased workforce wages, and cost increases for materials. Powertech (USA) commits to this requirement and will submit annual financial assurance updates for NRC Staff approval in accordance with Criterion 9 and NUREG-1569 on a timely basis.

5.7 Potential Environmental Impacts

Potential impacts have been evaluated with regard to the Proposed Action. After a complete site specific analysis of the potential impacts of the Proposed Action Powertech (USA) concludes that such potential impacts fall within the scope of the analysis and conclusions in NUREG-1910 regarding the South Dakota-Nebraska Region.

5.7.1 Potential Impacts of the No-Action Alternative

The potential impacts of a no-action alternative include the lost opportunity to produce a large resource of domestic uranium for use in the commercial nuclear fuel cycle from an ISL-amenable source. In addition, failure to license the Proposed Action will result in the failure to realize substantial positive effects on the economic growth of Custer and Fall River Counties through job creation and tax collections in the State of South Dakota. As discussed in the Cost-Benefit Analysis, below the project is expected to have significant positive economic impacts.

In 2007, total domestic U.S. uranium production was approximately 4.5 million pounds U3O8. During the same time domestic U.S. uranium consumption was approximately 51 million pounds U3O8. The project represents a significant new source of domestic uranium supplies that are essential to provide a continuing and economically viable source of nuclear fuel to domestic electric power electrical generation facilities thus reducing dependence on foreign energy supplies.

5.7.2 Potential Land Use Impacts of Proposed Action

Rangeland and pastureland are the primary land uses within the PAA and the surrounding 2 km review area. The PAA encompasses 10,580 acres (4,282 ha). Under the proposed action, this land will be temporarily converted from its previous use as rangeland and pastureland to ISL use on a progressive, "phased" basis. The PAA encompasses 10,580 acres, the land potentially disturbed by the Proposed Action will be approximately 68 acres (facilities, piping, ponds, well fields and roads) during the year proceeding operation. The potentially disturbed area during the life of the project (production to restoration) is estimated to increase over time to a maximum of 108 acres. If the maximum area for land application of treated wastewater is included in the footprint of the Proposed Action, then a maximum of additional 355 acres potentially would be affected by the Proposed Action for most of the project life. The maximum potential land disturbance at any given time is expected to be 463 acres. The CPP acreage is estimated at 6.7 (2.7 ha) located in the Burdock area. The satellite facility is estimated to consume 2.9 acres (1.2 ha) located in the Dewey area.

By way of reference, permitted areas for past and current-ISL operations have varied in size. Facilities' size range from about 2,552 acres (1,034 ha) for the proposed Crownpoint facility in McKinley County, New Mexico, to over 16,000 acres (6,480 ha) for the Smith Ranch property in Converse County, Wyoming. However, much of the permitted area of a site is undisturbed, and surface operations (wells, processing facilities) affect only a small portion of it (NUREG-1910, 2008). The land will likely experience an increase in human activity also contributing little to land disturbance. The disturbance associated with drilling, laying of pipeline, and facility construction will be limited and temporary as vegetation will be re-established through concurrent reclamation. The construction of new access and secondary roads will be minimized to the extent possible.

5.7.2.1 Potential Land Use Impacts of Operations

The primary land use within the PAA is rangeland. Operation of the project facilities will restrict the use of land as rangeland for the duration of the project. Following production and restoration, the PAA will be returned to rangeland use.
The Proposed Action will temporarily impact recreational use, which is limited primarily to large game hunting, within the project boundary., Within the PAA, hunting is currently open to the public on approximately 5,689 acres (2,302 ha). Approximately 240 acres (97.12) are owned by the Bureau of Land Management (BLM); the South Dakota Game Fish and Parks (SDGFP) lease around 3,069 acres (1,241 ha) annually of privately owned land and currently designate this acreage as walk-in hunting areas.

Additional land use impacts will include the disruption to livestock grazing within the PAA. Approximately 9.4 acres (3.8 ha) will be removed from grazing on the BLM land. This disturbance will be temporary in the area until the area is released for unrestricted use. Potential impacts include surface soil contamination from leaks or spills in well fields or from pipelines, but site reclamation will ensure that such impacts are temporary. Given the relatively small size of the area impacted by operations the exclusion of grazing from well field areas over the course of the project is expected to have minimal impact on local livestock production.

5.7.2.2 Land Use Regulations

Compliance with land use regulations of Custer and Fall River Counties in South Dakota as well as the most current version of BLM's Resource Management Plan for South Dakota will be necessary. The PAA is not located within lands withdrawn from mineral exploration and development. The Proposed Action will be reviewed by the BLM Field Office in Belle Fourche SD to ensure that the Proposed Action is compatible with management objectives for the area lands.

5.7.3 Potential Transportation Impacts

5.7.3.1 Potential Access Road Construction Impacts

There are only a few residences in the vicinity of the proposed project. Most of the land in the surrounding 2.0 km radius of the project is devoted to rangeland. The Dewey Road is the primary access road into the Proposed Action Area; this road runs primarily in a north- south direction through the PAA (Figure 3.1-1). Dewey Road is a county road and is maintained by the county. Secondary roads within the PAA will be constructed from the Dewey Road to the CPP, SF and header houses to the extent necessary. The PA will include establishing roads to individual wells. Off-site transportation routes will include federal, state, and county roads.

5.7.3.2 Potential Traffic Impacts

The predominant land use in the area is rangeland; other land uses include grazing, crop land, hunting and wildlife habitat. Due to the low population density within the region, the limited use of large machinery and vehicles and the infrequent movement of transport vehicles to and from the project site, no significant noise or congestion impacts are anticipated within the surrounding 2.0-km area during operations. There will be some increased traffic, noise and dust on the county road between the site and Edgemont during construction activities. However, these impacts will be minimal and temporary.

Radioactive materials have been shipped safely in this country for more than 50 years. As with other shipments, radioactive materials shipments have been involved in accidents. However, no deaths or injuries have resulted from exposure to their radioactive contents (USDOT, 1999). Powertech (USA) will design training programs and standard procedures in accordance with Department of Transportation (DOT) regulations found in CFR Titles 49 and 10 and will strictly enforce them in order to maintain compliance and to keep a safe transportation record. Powertech (USA) intends to provide relevant state and local authorities with information concerning transportation emergency response procedures.

5.7.3.3 Material Shipments

All shipments of materials and supplies to, from and within the Proposed Action Area will be transported by only properly licensed and certified drivers and subject to both federal and state transportation regulations. Four classifications of shipments will be sent or received during pre-operational and operational phases of the project:

- Non-radioactive materials such as: Construction materials, office supplies, process chemicals, and other related materials from vendors concerning onsite activities.
- Shipments of loaded resin to the CPP and eluted (stripped) resin to SF's.
- Shipments of dried and packaged yellowcake to a conversion facility.
- Shipments of waste material to an appropriate licensed facility.

Impacts would differ according to material type, quantities, and concentrations. The separate scenarios are discussed below.

The following section discusses the transportation risks of the four materials classified above. Mitigation and monitoring to eliminate or reduce the potential environmental impacts of a transportation accident are discussed in Section 5.8.

5.7.3.3.1 Shipments of Process Chemicals and Fuel

Over the course of the operational life of the facility several shipments of chemical, fuel, and supplies will be made per working day. Process chemicals delivered to the project will include carbon dioxide, oxygen, salt, soda ash, barium chloride, hydrogen peroxide, sulfuric acid, hydrochloric acid, caustic soda (sodium hydroxide), and fuel. All applicable DOT hazardous materials shipping regulations and requirements will be followed during shipment of process chemicals and fuel to prevent a possible transportation accident. Powertech (USA) will develop procedures to ensure compliance with applicable regulation to mininmize impacts to human health and the environment. Analyses of documented accidents involving shipments have shown that secure containers have prevented spills (NMA, 2007).

5.7.3.3.2 Ion Exchange Shipments

The project will have resin stripping facilities; therefore only shipments involving the barren or eluted resin will be transported to the PAA. The consequences are likely to be lower for trucks transporting barren or eluted resin because the risk of contamination is minimal. Both barren and eluted resin shipments will be handled in accordance with NRC and DOT regulations. Powertech (USA) will transport loaded and eluted resin back and forth between the Dewey satellite and the Burdock CPP. This transportation will occur on-site at an estimated rate of one loaded resin truck from the SF to the CPP and one eluted from the CPP to the SF per day.

The same general shipping procedures outlined for the shipment of yellowcake will be followed for resin shipments.

The ion exchange resin will be shipped to and from the project in a tank truck. The NRC calculated the probability of an accident involving a truck transporting uranium-loaded resin from a satellite plant to a main processing plant at 0.009 in any year (U.S. Nuclear Regulatory Commission, 1997a).

The main environmental impacts from an accident involving the shipment of ion exchange resin would potentially be primarily impacts to the top soil in the area contaminated by the spill and the subsequent modification to the vegetation structure and the salvage of the top soil. This is scenario would only take place if drums were ruptured.

5.7.3.3.3

5.7.3.3.4 Yellowcake Shipments

The yellowcake will be loaded into a gasketed and sealed 55-gallon (208-L) drums which will be trucked to a conversion facility via qualified and certified carrier. Specific routes are to be determined by contract with the carrier. The carrier will meet all safety controls and regulations promulgated by 10 CFR 71.5. With a production rate of 1,000,000 lbs per year at the PAA, shipments are estimated to weigh approximately 40,000 lbs per load and would require an estimated 25 shipments per year. Smaller or partial loads could require additional shipments.

According to NUREG/CR 6733 earlier analyses concluded that the probability of a truck accident, involving the transport of yellowcake, for any given year was 11 percent for each uranium extraction facility. This calculation used average accident probabilities (4.0 × 10-7/km rural interstate, 1.4 × 10-6/km rural two-lane road, and 1.4 × 10-6/km urban interstate) that are considered conservative compared to other NRC transportation risk assessment (NUREG/CR 6733).

The worst case accident scenario involving yellowcake shipments would involve the release of yellowcake into the environment due to the breach of one or more drums containing yellowcake during transportation. In an accident involving a similar ISL facility and the shipment of yellowcake through Kansas (SRI International, 1979b), approximately 1,800 pounds or 4 percent of the yellowcake onboard the truck was spilled; no dose estimates were reported, the spill was quickly contained and all the yellowcake was thought to have been recovered.

Yellowcake shipments will be classified as Low Specific Activity (LSA) material and will be handled in accordance with NRC and DOT regulations. Powertech (USA) will develop an Emergency Preparedness Program that will be implemented should a transportation accident occur. The team training will provide technical instruction on field monitoring, sampling, decontamination procedures, communication, and other related skills necessary to safely handle a transportation emergency concerning shipments of yellowcake.

Before a shipment is approved for transportation, proper packaging including Marking/Labeling and Placarding must be accomplished within DOT regulations; Inspections of the vehicle and load will be performed; routing the shipment to minimize radiological risk and contacting Emergency Preparedness personnel are among the duties performed before a shipment would be approved to leave the facility.

5.7.3.3.5 Shipments of Waste Materials

Depending on classification of waste material the waste will be sent to different disposal sites. The categories are:

- Non-hazardous solid wastes shipped to a permitted landfill
- Hazardous solid or liquid wastes shipped to a permitted hazardous waste disposal facility
- 11e.(2) Byproduct material disposed of at a licensed or permitted facility

Most of the solid waste shipping will occur during the site reclamation and decommissioning phases. The probability of an accident while transporting 11e.(2) waste for any given trip is similar to the probability discussed in Section 5.7.3.3.3. The potential risks, however, for exposure are less because 11e.(2) waste is generally less radioactive than dried yellowcake and much of the waste will consists of solid material that in the event of an accident would be easy to contain. All applicable DOT shipping regulations and requirements will be followed before and during shipment of 11e.(2) wastes to prevent a possible transportation accident.

Liquid waste meeting the criteria of 11e.(2) will be disposed of via a waste disposal well (WDW) all applicable EPA and NRC regulations will be complied with. Transportation of liquid 11e.(2) will be accomplished via a pipeline or tanker truck from CPP area to the WDW.

5.7.3.3.5.1 Potential Post Operation Transportation Impacts

Before the on-site road reclamation begins, landowners will be contacted and given the option to retain the roads for their private use or have the roads reclaimed by Powertech (USA). If the roads are deemed beneficial to others (i.e., hunters, ranchers and residents) and the landowner agrees, the roads will not be reclaimed. Only roads related to the PA will be reclaimed.

5.7.3.3.5.2 Potential Cumulative Transportation Impacts

The cumulative volume of traffic associated with the PA is anticipated to be low, due to the relatively concentrated nature of the resources and the small workforce associated with ISL operations (NUREG-1910, 2008). Given this is the only ISL operation located in the state, and few industrial operations within the immediate region, therefore the cumulative transportation impacts will be insignificant.

5.7.4 Potential Geologic and Soil Impacts

5.7.4.1 Potential Geologic Impacts

Geologic impacts from the project are expected to be negligible or non-existent. The project is not expected to have a significant effect on ground subsidence or matrix compression because the net withdrawal of fluid (bleed) from the extraction zone is generally on the order of 3 percent or less, and the ISL process does not remove matrix material or structure. After restoration is complete, the groundwater levels are expected to return to pre-operational levels, and should therefore not have any significant effects on the quantity of groundwater.

Impacts are more likely to occur from other geologic factors such as earthquakes. As discussed in Section 7.6, the maximum magnitude earthquake estimated for the PAA is a VII on the Modified Mercalli Scale, corresponding to a Richter magnitude of 6.1

Due to the design of the project, no impacts are expected to subsurface geological strata. (NUREG-1910, 2008).

5.7.4.2 Potential Soil Impacts

There are two main drainage basins located in the PAA; each of the drainages have different soil types. The soil mapping unit descriptions are in Section 3.3. The Beaver Creek basin is composed of Haverson loam, and has 0-2 percent slopes throughout the drainage. The Cottonwood Gallery basin is composed of Barnum silt loam in the south half of the drainage and Barnum-Winetti complex, and has 0-6 percent slopes. The old mine pits were also classified as Barnum silt loam and Barnum-Winetti complex.

The ISL operation will disturb approximately 68 acres (27 ha) (facilities, piping, ponds, well fields and roads) in year one. Potential impacts include:

These impacts potentially could occur via:

- Compaction
- Loss of productivity
- Loss of soil
- Salinity
- Soil contamination
- Clearing vegetation
- Compaction
- Excavation
- Leveling
- Redistribution of soil
- Stockpiling

Severity of impacts to soil is dependent upon type of disturbance, duration of disturbance and quantity of acres disturbed. Construction and operation activities have the potential to compact soils. Soils most sensitive to compaction, clay loams, are not present within the PPA, however; due to the use of heavy machinery and high volume within certain area some soils have the potential for compaction. Compaction of the soil can lead to decreased infiltration thereby increasing runoff. Soils compacted during construction and operations will be restored (i.e., disced and reseeded) as soon as possible following use.

Based on the soil mapping unit descriptions, the hazard for wind and water erosion within the PAA varies from negligible to severe. The potential for wind and water erosion is mainly a factor of surface characteristics of the soil, including texture and organic matter content. Given the very fine and clayey texture of the surface horizons throughout the majority of the PAA, the soils are more susceptible to erosion from water than wind. See Table 7.5-7 for a summary of potential wind and water erosion hazards within the PAA.

During land application disposal, there could be potential impacts to the soil and crops from total dissolved solids (TDS) and electrical conductivity (EC) values in the water to be used to irrigate crops as shown in Table 5.7-1. These levels pose low to moderate risk to the growth of moderately sensitive crops such as alfalfa and corn. The SAR levels are low and pose little risk to the infiltration of rain or snowmelt. There could be some salt deposition at the surface, however maintaining maximum vegetative cover will reduce the possibility of undesirable species. During the irrigation season, water application rates will be adjusted to optimize both evaporation and crop production.

Table 5.7-1 AR, ESP and RSC Calculations for Dewey and Burdock End-of-Mining Ground Water Quality([a])

Constituent	Dewey					Burdock				
	(mg/L)	(meq/L)	ESP[(1)]	RSC[(2)]	SAR[(3)]	(mg/L)	(meq/L)	ESP[(1)]	RSC[(2)]	SAR[(3)]
CO_3	0.5	0.02				0.50	0.02			
HCO_3	25	0.41				25.00	0.41			
Cl	1,300	36.67				1,300	36.67			
SO_4	1,000	20.82				1,800	37.48			
Na	270	11.74				190	8.26			
Ca	730	36.43				970	48.40			
Mg	120	9.87	2.29	-45.87	2.44	220	18.09	0.85	-66.07	1.43
K	20	0.51				10	0.26			
Total Ion Bal.		0.54					0.29			
SAR (measured)	4.9					2.8				
pH (s.u.)	6.5-7.5					6.5-7.5				
TDS (mg/L)	4,500					4,500				
Elec. Cond. (µS/cm)	3,000					4,000				
As	0.01					0.01				
V	<10					6				

([a]) - Estimated by Powertech (USA) based on results of laboratory scale leach tests conducted on ore samples from the Fall River and Lakota sites, as well as from historical end-of-mining water quality data from other ISL sites in Wyoming and Nebraska, with adjustments as necessary to account for planned post-mining water treatment(s).

- ESP = Exchangeable Sodium Percentage. Empirical relationship from Withers and Vipond (1980).

$$ESP = \frac{100(-0.0126 + 0.01475 * SAR)}{1 + (-0.0126 + 0.01475 * SAR)}$$

- RSC = Residual Sodium Carbonate (meq/L).

$$RSC = ([CO_3] + [HCO_3]) - ([Ca] + [Mg])$$

- SAR = Sodium Adsorption Ratio.

$$SAR = \frac{[Na]}{\sqrt{([Ca] + [Mg]) / 2}}$$

Facility development could displace topsoil, which could adversely affect the structure and microbial activity of the soil. Loss of vegetation would expose soils and could result in a loss of organic matter in the soil. Excavation could cause mixing of soil layers and breakdown of the soil structure. Removal and stockpiling of soils for reclamation could result in mixing of soil profiles and loss of soil structure. Compaction of the soil could decrease pore space and cause a loss of soil structure as well. This could result in a reduction of natural soil productivity. Increased erosion and decreased soil productivity may cause a potential long-term declining trend in soil resources. Long-term impacts to soil productivity and stability could occur as a result of large-scale surface grading and leveling, until successful reclamation is accomplished. Reduction in soil fertility levels and reduced productivity could affect diversity of reestablished vegetative communities. Infiltration could be reduced, creating soil drought conditions. Vegetation could undergo physiological drought reactions (Lost Creek, 2007).

Overall, the potential environmental impacts to the soil within the PAA may be increased compared to areas outside the PAA but typically will not result from the ISL process itself, but rather from ancillary activities such as waste disposal and construction. In the past, ISL facilities adopt best construction practices to prevent or dramatically decrease erosion (NUREG-1910). Many facilities have been operated to minimize erosion and surface disturbance and then assiduously restored affected soils effectively leaving little impact on soils (NMA, 2007).

5.7.4.3 Monitoring Well Rings, Well Field and Associated Piping

The scale of monitoring well rings will have little impact on the amount of soil disturbance. Differences in disturbance to soil will depend on area of monitoring well ring and natural growth of vegetation within the specific well field. During construction of each well field, drilling activities will occur only on a small percentage of an ISL site at any one time (HRI, 1997a). The amount of land disturbed at any time typically will range from 100 to 400 acres (EPA 2007); however, some ISL sites may be larger or smaller. Disturbance associated with drilling and pipeline and facility installation normally will be limited, as the affected area can be reclaimed and reseeded in the same season. Vegetation normally will be re-established over these areas within 2 years (NMA, 2007).

Subsurface soils will be excavated and removed from their native location. Excavated soils (drill cuttings) are returned to mud pits as Technologically Enhanced Naturally Occurring Radioactive Material (TENORM). Naturally occurring radioactive material with radionuclide concentrations increased by or as a result of past or present human practices.

Movement of drilling and construction equipment and installation of wellheads, piping systems, and other facilities will disturb small areas of surface soil. Vehicle movement could cause compaction, rutting, and other disturbances to the surface soil and rocks. Depending on the intensity and duration of construction activities, compaction and erosion of surface soil could alter drainage and cause accelerated erosion and degradation of surrounding surface water resources. However, good management practices likely will minimize, if not eliminate, any such potential impacts (NMA, 2007).

5.7.4.4 Wastewater Retention Ponds

Only very shallow surface soils in the immediate area could be disturbed during construction of the waste retention ponds, though excavated soils from other parts of the site typically will be imported and used to construct the foundation and walls of the ponds. Surface soils in the area will be compacted from the overlying weight of the pond.

Movement of construction equipment could disturb small adjacent areas of surface soil, and vehicle movement to and within the construction site could cause compaction, rutting, and other disturbances to the surface soil and rocks. Depending on the intensity and duration of construction activities, compaction and erosion of surface soil could alter drainage and cause accelerated erosion and degradation of surrounding surface water resources. However, good management practices will likely minimize any such potential impacts (NMA, 2007).

Wastewater produced during operations typically will be handled in one or a combination of two ways: deep well injection or land application. Storage ponds of suitable capacity will be needed for deep-injection well disposal and land application. Where such wells are not available, land application is the only disposal option. The size of the storage ponds required and the land impacts are significantly different depending on the method of disposal utilized.

5.7.4.5 Waste Disposal Well

As deep-disposal wells are drilled, there will be disruption of soil, rock formation, and water flow processes; however, these potential impacts are minor and are similar to common drilling for water, oil and gas. EPA/state UIC regulations and permitting guidance require an evaluation of the seismic risk of a potential disposal well site, including evaluation of the potential pressure impacts to the injection zone. As such, current regulations are in place to ensure the seismic stability of the selected injection site. Changes caused by thermal (heat caused by drilling), chemical (possible reaction caused displaced chemicals during drilling), and mechanical alterations will be negligible and similar to most drilling projects. As the Class I or V UIC deep-disposal well permitting process is intended to ensure protection of USDWs, ISL solutions destined for deep-injection well disposal will require compliance with EPA/state UIC regulations and, as such, the potential impacts will be negligible (NMA, 2007).

5.7.4.6 Well Fields

In addition, the injection of treated groundwater as part of uranium recovery or as part of restoration of the production zone is unlikely to cause changes in the underground environment except to restore the water quality consistent with baseline or other NRC approved limits and to reduce mobility of any residual radionuclides. Further, industry standard operating procedures, which are accepted by NRC and other regulating agencies for ISL operations, include a regional pump test prior to licensing, followed by more detailed pump tests after licensing for each individual area where uranium will be recovered prior to its production. Any potential variations in hydrogeology, due to disruption of soil or rock formation will be assessed and taken into account prior to commencing operations to ensure that operations will not impact adjacent, non-exempt drinking water resources in the region. Powertech's (USA) well field designs are substantially similar if not identical to those assessed in NUREG-1910. As a result, the potential impacts on soils from well fields will be within the scope of NUREG-1910's analyses and conclusions.

5.7.4.7 Uranium Processing Facilities

Standardized ISL processing facilities as assessed in NUREG-1910 will not impact geology and soils at the site after the construction of the facilities. An impact will occur only if there is an accident or a malfunction that spills or emits processing chemicals, leach solutions, loaded IX resins or yellowcake products (i.e., slurry or dried concentrate) onto site surface soils. Powertech's (USA) uranium processing facility designs are substantially similar if not identical to those assessed in NUREG-1910. As a result, the potential impacts on soils from such facilities will be within the scope of NUREG-1910's analyses and conclusions.

5.7.4.8 Potential Decommissioning Impacts to Geology and Soils

Decommissioning of ISL facilities includes: (1) dismantling process facilities and associated structures, (2) removing buried piping, and (3) plugging and abandoning wells using accepted practices, (4) activities associated with land reclamation and cleanup of contaminated soils. Before decommissioning and reclamation activities begin, the licensee is required to submit a decommissioning plan to NRC for review and approval. The licensee's spill documentation, an NRC requirement, would be used to identify potentially contaminated soils requiring offsite disposal at a licensed facility. Any areas potentially impacted by operations would be included in surveys to ensure all areas of elevated soil concentrations are identified and properly cleaned up to comply with NRC regulations at 10 CFR Part 40, Appendix A, Criterion 6-(6). Most of the impacts to geology and soils associated with decommissioning are temporary and SMALL. Because the goal of decommissioning and reclamation is to restore the facility to 3 preproduction conditions to the extent practical, the overall long-term impacts to the geology 4 and soils would be SMALL (NUREG-1910, 2008). Powertech (USA)'s decommissioning plan has been prepared in accordance with NRC regulations and guidance as assessed in NUREG-1910. As a result, the potential impacts on soils from such activities will be within the scope of NUREG-1910's analyses and conclusions as the site can be released for unrestricted use.

5.7.5 Potential Water Resource Impacts

5.7.5.1 Potential Surface Water Impacts

The average annual runoff for this region is higher than that for the Wyoming West Region, therefore potential surface water impacts may be slightly higher in the Proposed Action Area (USGS, 2008 in NUREG-1910, 2008). The water quality of storm water is regulated under permits issued by South Dakota's Surface Water Quality Program in Pierre. Impacts to wetlands are negligible (See Section 5.4.4.2) and will be addressed through consultations and the permitting process (NUREG-1910, 2008). The surface water impacts overall would be small to moderate. All activities that could potentially affect surface water will be undertaken in such a way as to comply with applicable state and federal regulations and conditions of permit; through the use of best management practices and mitigation measures impacts to water quality will be reduced to small and/or moderate and determined by site specific conditions (NUREG-1910, 2008).

5.7.5.2 Potential Surface Water Impacts from Construction

Construction activities within the well fields, along the pipeline courses and roads, and at the process plant have the potential to increase the sediment yield of the disturbed areas. The impacts from increased sedimentation will be minimal because of the short-term nature of the disturbance (areas will be concurrently reclaimed) and the area of disturbance is small compared to the total drainage basin of Angostura Reservoir (total area 7143 mi2) and because of the lack of dependable surface water supplies (DENR, 2007). A slight increase in sediment yields and total runoff can be expected during final reclamation; however, well field decommissioning and reclamation activities via best management practices and mitigation measures utilized throughout the life of the project will help to reduce the impacts. No direct disturbance to any wetlands or water sources is planned at this time. If, in the future, the proposed action should involve an impact to a jurisdictional wetland area or water source, the appropriate actions will be taken in accordance with Section 404 of the Clean Water Act and ACE regulations.

"Potential indirect impacts of ISL operations could include increased sediment deposition in streams, which could alter stream morphology and degrade the suitability of channel substrate for aquatic organisms. However, as stated previously, this issue is addressed by NPDES storm water requirements, and good management practices likely will minimize, if not eliminate, any such potential impacts" (NUREG-1910, 2008). Indirect impacts to surface water will be limited to uncommon precipitation or runoff events (e.g., a flood event).

There were 20 potential wetland sites evaluated by the ACE; the determination rendered four of the 20 evaluated as Jurisdictional sites (see Appendix 5.4-H). Descriptions of the jurisdictional determination: Ephemeral Tributary to Beaver Creek, Ephemeral Tributary to Pass Creek, Pass Creek (NonRPW), Beaver Creek (Perennial RPW). Beaver Creek is the only perennial stream within the proposed PAA and the rest of the natural water flow is ephemeral. Of the jurisdictional determinations within the Proposed Action Area, impact is expected to be small and none are expected to experience direct impact from the pre-operational or operational activities. Erosion potential is present due to the possible construction of the wells near the drainage area; however, disturbance is expected to be mild and short-term.

An old mine pit located at Waypoint 37 was determined to be a non-wetland area. Although surface water was present, there was no hydrophytic vegetation or hydric soils. This old mine pit is also located along a disturbance area. The concentration of old mine pits along the eastern edge of the permit area contained small PUB wetlands (0.175 acres) that are a product of the old mine pits, that could be impacted by disturbance areas located along the old mine pits.

Mitigation measures employed in order to minimize potential impacts may include: best soil management practices (i.e., silt fencing, straw bales) if crossing the water body is necessary, timing of crossing will be evaluated, and only temporary crossing may be necessary, and type of equipment working near water body will be considered. Potential impacts to surface waters from the construction of an ISL facility would be expected to be SMALL based on the application of federal and state clean water regulations in conjunction with the use of best management practices (NUREG-1910, 2008).

ISL operations do not involved the consumption of surface waters. Nor do the operations proposed require a long- term discharge to surface waters. For these reasons, no significant impacts to surface water quantity and use are anticipated.

5.7.5.3 Potential Surface Water Impacts from Operations

Potential impacts from accidental spills or permitted temporary discharge to surface water may include the release of process materials into the environment or a release or spill from the operation or well field (e.g., handling of fuels, lubricant, oily wastes, chemical wastes, sanitary wastes, herbicides, and pesticides). Surface water monitoring and spill response procedures will limit the impact of potential spills to surficial aquifers. The impact that may result from a spill is dependent upon several considerations such as: size of spill, remediation success, designated use of the surface water, location of spill relative to surface water, and any relative contribution an aquifer discharge may have to the surface water (NUREG-1910, 2008). A Storm Water Pollution Management Plan (SWMP) will be part of the NPDES permit issued and will describe potential sources of storm water contamination from the facility. The SWMP will include routes by which spills may leave the facility and the best management practices to be implemented as preventative measures to control storm water contamination (NUREG-1910, 2008).

Most ISL operations extract slightly more groundwater than they re-inject into the uranium bearing formation. The groundwater extracted from the formation could result in a depletion of flow in nearby streams and springs if the ore-bearing aquifer is hydraulically connected to such features. However, because most, if not all ISL operations are expected to occur where the ore-bearing aquifers are confined, local depletion of streams and springs is unlikely, and potential impacts would be anticipated to be SMALL (NUREG-1910, 2008).

Any water disposed of via land application methods must be treated in compliance with any established state and federal established concentration levels for specified constituents. According to 10 CFR Part 20, the NRC requirement is that the public and occupation dose limits are met during and post land application. An accumulation of some constituents and dissolved solids may develop within the soils and may potentially have an indirect impact on surface water. The degree of the potential impacts again, would depend on factors such as actual evapotranspiration rates, irrigation rates, precipitation quantities and sorpitive properties of specific soils with respect to constituents considered (NUREG-1910, 2008). Permit requirements will be in place to assure mitigation should any accumulations of residuals remain upon completion of the operations. At that time the land application areas would be subject to land surveys during decontamination efforts. If accumulation occurs, that does not meet permit conditions is discovered, the areas in exceedance will be remediated to meet the NRC regulations, consequently; potential impacts from permitted land application will be SMALL (NUREG-1910, 2008).

5.7.5.4 Potential Groundwater Impacts from Production Operations

During ISL operations, the following is a list of potential impacts to groundwater: (1) Alteration of groundwater quality from the addition of the proposed lixiviant oxygen and carbon dioxide to the groundwater in the exempted aquifer, (2) the addition of chloride to the groundwater by displacement from the ion exchange resin during the uranium loading process, (3) and the interaction of these chemicals with the mineral and chemical constituents of the aquifer being mined, primarily the oxidation of the pyrite in the ore body to form solubilized sulfate ion. The result is that during the proposed action, the concentration of most of the naturally occurring dissolved constituents in the ore zone(s) will be higher than their concentrations in the pre production groundwater. The ISL process does not introduce constituents that are not already present within the groundwater. Procedures proposed in this application are designed to provide early detection of and to provide for remediation any excursions of leach fluids to adjacent non exempt USDWs. These procedures are consistent with those recommended in NUREG-1910 to address potential groundwater impacts; therefore will be no adverse impacts on human health and the environment from affected groundwater within the production zone.

5.7.6 Monitoring

To assess the potential impacts from production and restoration operations on local groundwater, the background water levels in regional monitoring wells installed by Powertech (USA) will be monitored before production and as required during operations.

5.7.6.1 Potential Impacts of Production on Ore Zone Groundwater Quality

Potential environmental impacts to groundwater are changes to water quality in well fields within the exempted aquifer. The impact, in and of itself, it is of limited significance, due to the fact that the groundwater quality is very poor prior to ISL operations; due to the presence naturally occurring radionuclides, heavy metals, and other constituents that exceed EPA and/or state drinking water limits. Accordingly, the exempted aquifer is not and can never serve as a USDW (HRI, 1997; NMA, 2007).

Powertech (USA) has proposed to use gaseous oxygen and carbon dioxide lixiviant. The interaction of the lixiviant with the mineral constituents of the exempted ore zone results in a slight increase in trace elements and primary constituents of sulfate, chloride, cations and TDS above pre production levels. There is no introduction of non-naturally occurring constituents from the leach fluids into the ore body.

The uranium present in the ore zone pre-operations is solubilized by oxidation via the ISL process. Uranium, when oxidized to the soluble valence, reacts with the bicarbonate ions to form a stable, soluble anion, uranyl bicarbonate. The dissolved oxygen in the leach fluid also oxidizes the pyrites (sulfides) to increase the concentration of sulfate (SO4) ions in solution. The loading of uranyl bicarbonate ions onto the resin displaces chloride ions into the leach solution. Therefore, the leach process which recycles groundwater back to the ore zone increases the concentration of sulfate and chloride anions into the leach solution. The increase in sulfate and chloride anions in the leach solution increases the concentrations of sodium, calcium, potassium and magnesium cations in solution. These cations are exchanged off the clays within the ore body to balance the ion charges in the leach solution. Since these cations and anions are the principal constituents of TDS, therefore the TDS increases.

5.7.6.2 Potential Groundwater Impacts from Land Application

The wastewater applied to the land will be treated to meet EPA Primary Drinking Water Standards and NRC effluent criteria for radionuclides as referenced in 10 CFR part 20 Appendix B. Therefore, potential adverse impacts to groundwater are not anticipated.

Data from test pits 1, 2 and 5 were used to develop the soil profile used in the SPAW modeling for the Dewey site. The logs for these test pits indicated that bedrock was encountered at depths of 9 feet, 11 feet, and 8.5 feet respectively below the ground surface. The composite soil profile used to model the soil at the Dewey site had a total depth of 9.83 feet. The results of the SPAW modeling indicated that the soil moisture content at the base of this soil profile was less than field capacity for all cases that were modeled (28 15-year simulations) and that there was no percolation beyond the base of the soil profile (Appendix 5.7-A). Therefore, it is assumed that there would be no lateral movement of water along the bedrock surface, and no vertical movement of water into the bedrock, and therefore no leaching of trace elements beyond the base of the soil profile.

Data from test pits 8, 9 and 10 were used to develop the soil profile used in the SPAW modeling for the Burdock site. The logs for these test pits indicated that bedrock was encountered at depths of 7 feet and 5 feet below the ground surface in test pits 8 and 9. Test pit 10 was excavated to a total depth of 12 feet, with a clayey silt layer from 2 feet to 12 feet below the ground surface. The composite soil profile used to model the soil at Burdock had a total depth of 8 feet. The results of the SPAW modeling indicated that the soil moisture content at the base of this soil profile was also less than field capacity for all cases that were modeled (28 15-year simulations) and that there was no percolation beyond the base of the soil profile. Again it is assumed that no lateral movement of water would occur along the bedrock surface, and that water would not move vertically into the bedrock, and therefore there would be no leaching of trace elements beyond the base of the soil profile.

Based on the above information, there will be no migration pathway of waste water constituents to groundwater beneath the land application sites, thereby eliminating any potential of exposure and risk to human health and the environment.

5.7.6.3 Potential Groundwater Impacts from Deep Well Disposal Below Production Aquifer

Deep well injection involves the pumping of waste fluids into a deep confined aquifer. Aquifer water quality in the deep confined aquifer is often poor (e.g., high salinity or total dissolved solids) and does not meet drinking water standards. Licensees must obtain an UIC permit from EPA or the appropriate state agency. The approval process verifies that site-specific and regional characteristics limit the potential for contamination of local drinking water sources. This is accomplished by the licensee providing data that the aquifer is hydraulically separated from the overlying aquifer systems. “Under these conditions, the potential environmental impacts would be SMALL” (NUREG-1910, 2008). NRC staff may also review the UIC application, even though the EPA or state give final approval. NRC has approved deep well injection for specific ISL sites as a method to dispose of particular process fluids such as reverse osmosis brine”.

The potential environmental impacts of injection of leaching solutions into deep aquifers below ore-bearing aquifers would be expected to be SMALL, if water production from deep aquifers is not economically feasible or the groundwater quality from these aquifers is not suitable for domestic or agricultural uses (e.g., high salinity), and they are confined above by sufficiently thick and continuous low permeability layers. The impacts of discharging wastes to deep disposal well during restoration are expected to be similar to the impacts of these waste management practices during operations-SMALL (NUREG-1910, 2008)

5.7.6.4 Potential Groundwater Impacts from Aquifer Restoration

Groundwater consumption is the primary impact of concern when considering aquifer restoration and waste management.

Groundwater transfer has minimal impact concerning groundwater consumption by replacing recovered well field groundwater with near baseline quality water. Whereas groundwater sweep has a larger impact since the process involves extracting the recovered well field water and pulling unaffected water into the aquifer to take its place. When utilizing RO, 70 to 99 percent of the water is suitable for reinjection into the formation, depending on whether a brine concentrate is used. This lowers groundwater consumptive use substantially during aquifer restoration.

All well fields do not undergo restoration simultaneously. A deliberate phased approach is utilized to keep groundwater impacts to a minimum throughout the life of the operation. Potential environmental impacts are affected by the restoration techniques chosen, the severity and extent of the contamination, and the current and future use of the production and surrounding aquifers in the vicinity of the ISL facility. The potential environmental impacts of groundwater consumption during restoration could be SMALL to MODERATE depending on site-specific conditions. Site-specific impacts also would depend on the proximity of water users' wells to the well fields, the total volume of water in the aquifer, the natural recharge rate of the production aquifer, the transmissivity and storage coefficient of the production aquifer, and the degree of isolation of the production aquifer from aquifers above and below (NUREG-1910, 2008).

Deep well injection is one of the most common methods to dispose of the more heavily concentrated wastewater. Brine water treated via RO may also be disposed of via deep well injection. Aquifers utilized for deep disposal must meet federal and state standards such as: the aquifer must have poor water quality, low water yields, or be economically infeasible for production. Underground injection of wastewater requires an EPA permit and approval from the NRC. Impacts from deep well disposal are expected to be SMALL (NUREG-1910, 2008).

5.7.6.5 Potential Impacts of Groundwater Consumption During Operations and Restoration

The majority of groundwater used in the ISL process will be treated and injected. Based on a median case of bleed of one percent of 2,000 gpm (20 gpm), the potential impacts from consumptive use of groundwater in the Fall River and Lakota aquifers are calculated below. There are separate calculations for the Fall River aquifer assuming pumping at the first proposed well field at the Dewey Site, and for the Lakota aquifer assuming pumping at the first proposed well field at the Burdock Site.

The potential impacts due to drawdown are calculated at the locations of the nearest wells outside the proposed Permit Boundary Area that are expected to remain active during the life of the Project

5.7.6.6 Drawdown Estimates

The Theis analytical solution includes the following assumptions (Driscoll, 1986):

The aquifer is homogeneous and isotropic (same hydraulic conductivity everywhere).

- The aquifer is confined with uniform thickness and has infinite extent.

- No recharge to the aquifer occurs.
- The pumping well is fully penetrating and receives water from the full thickness of the formation.
- All water removed from the well comes from aquifer storage which is discharged instantaneously when the head is lowered.
- The piezometric surface is horizontal prior to pumping.
- The well is pumped at a constant rate.
- The pumping well diameter is small so well bore storage is negligible.

Possible barrier boundaries for the aquifer system include the respective outcrops of the Fall River and Lakota formations generally east and north of the property boundary, as well as the Dewey Fault to the north and east of the property boundary. However, the Dewey Fault is considered likely to terminate both the Fall River and Lakota aquifers at some distance to the west. Therefore, just the outcrop was assumed to be a straight line barrier boundary and modeled with "image" pumping wells (e.g. Fetter, 1988) having the same pumping rates as the production wells for the Fall River and Lakota aquifers. A spreadsheet developed by the U.S. Geological Survey to calculate drawdown according to the Theis equation (Halford and Kuniansky, 2002) was used to make the confined aquifer prediction calculations.

5.7.6.7 Drawdown Impact – Fall River Aquifer

The following is a summary of available aquifer parameter (transmissivity, storativity) determination in successful pumping tests.

- 1979 TVA tests at Burdock area (Bogg and Jenkins, 1980):
  - Formation transmissivity: 54 ft^2/day
  - Formation storativity: 1.4 x 10^{-5}
- 2008 Powertech (USA) tests at Dewey area (Knight Piésold, 2008):
  - Formation transmissivity: 255 ft^2/day
  - Formation storativity: 4.6 x 10^{-5}

To quantify the impact of the Project on the Fall River Formation aquifer the following assumptions were used together with the range of aquifer parameters above:

- Production/restoration: 8 years
- Average net consumptive use: 20 gpm
- Location of pumping centroid: NW ¼ of Section 32, T6S, R1E
- Distance from pumping well to barrier boundary (Fall River outcrop): 14,610 ft
- Observation radius: 15,075 feet (nearest domestic well, Hydro ID = 18), SW ¼ of SW ¼ of Section 9, T7S, R1E
- Image well observation radius: 39,350 ft

For the 1979 TVA test parameters, the calculated drawdown at the nearest domestic well after 8 years of pumping at 20 gpm due to the pumping well alone is 26.8 feet. The calculated drawdown at the nearest domestic well due to the image well is 16.0 feet. Thus the estimated drawdown at the nearest domestic well is 42.8 feet after 8 years of continuous pumping at a rate of 20 gpm.

For the 2008 Powertech (USA) test parameters, the calculated drawdown at the nearest domestic well after 8 years of pumping at 20 gpm due to the pumping well alone is 6.1 feet. The calculated drawdown at the nearest domestic well due to the image well is 3.8 feet. Thus the estimated drawdown at the nearest domestic well is 9.9 feet after 8 years of continuous pumping at a rate of 20 gpm.

Therefore, based on available pumping test data, the range of possible drawdown estimates at the nearest domestic well, located 15,075 feet from the approximate center of pumping is 9.9 to 42.8 feet.

5.7.6.8 Drawdown Impact – Lakota Aquifer

The following is a summary of available aquifer parameter (transmissivity, storativity) determination in successful pumping tests.

- 1979 TVA tests at Burdock area (Bogg and Jenkins, 1980):
  - Formation transmissivity: 190 ft^2/day
- Formation storativity: 1.8 x 10-4
- 1982 TVA tests at Dewey area (Boggs, 1983):
  - Formation transmissivity: 590 ft^2/day
  - Formation storativity: 1.0×10^{-4}
- 2008 Powertech (USA) tests at Burdock area (Knight Piésold, 2008):
  - Formation transmissivity: 150 ft^2/day
  - Formation storativity: 1.2×10^{-4}

To quantify the impact of the Project on the Lakota Formation aquifer the following assumptions were used:

- Production/restoration: 8 years
- Average net consumptive use: 20 gpm
- Location of pumping centroid: SW ¼ of Section 11, T7S, R1E
- Distance from pumping well to barrier boundary (Lakota outcrop): 17,610 ft
- Observation radius: 10,915 feet (nearest domestic well, Hydro ID = 13) NE ¼ of NE ¼ of Section 4, T7S, R1E
- Image well observation radius: 36,170 ft.

For the 1979 TVA test parameters, the calculated drawdown at the nearest domestic well after 8 years of pumping at 20 gpm due to the pumping well alone is 6.6 feet. The calculated drawdown at the nearest domestic well due to the image well is 2.9 feet. Thus the estimated drawdown at the nearest domestic well is 9.5 feet after 8 years of continuous pumping at a rate of 20 gpm.

For the 1982 TVA test parameters, the calculated drawdown at the nearest domestic well after 8 years of pumping at 20 gpm due to the pumping well alone is 3.0 feet. The calculated drawdown at the nearest domestic well due to the image well is 1.8 feet. Thus the estimated drawdown at the nearest domestic well is 4.9 feet after 8 years of continuous pumping at a rate of 20 gpm.

For the 2008 Powertech (USA) test parameters, the calculated drawdown at the nearest domestic well after 8 years of pumping at 20 gpm due to the pumping well alone is 8.7 feet. The calculated drawdown at the nearest domestic well due to the image well is 3.9 feet. Thus the estimated drawdown at the nearest domestic well is 12.6 feet after 8 years of continuous pumping at a rate of 20 gpm.

Therefore, based on available pumping test data, the range of possible drawdown estimates at the nearest domestic well, located 10,915 feet from the approximate center of pumping is 4.9 to 12.6 feet.

5.7.6.9 Potential Impacts from Simultaneous Operational and Restorational Groundwater Consumption

5.7.6.9.1 Operational Water Use

During ISL operations (including both production and restoration) nominal bleed rates of .5-1 percent are expected to be maintained over the life of the project. Instantaneous rates may vary in the range of 0.5 percent to 3 percent for short durations, from days to months. All effluent systems for treating bleed streams are designed for continuous operation at the maximum bleed rate of 3 percent. However, over the life of the project, a reasonable estimate of .5-1 percent, or slightly less, bleed is believed appropriate and sufficient to maintain a the cone of depression necessary within any production or restoration activity In situ mining circulates significant quantities of water through the ore zone but consumes only a small fraction of that amount because most water is reinjected back into the deposit. During operations, 0.5 to 3 percent of the solution extracted from the aquifer will be “bled” from the system to ensure a cone of depression is maintained and that no leach fluids are released from the production area.

It is anticipated that no more than two well fields, typically one at the Dewey site and one at the Burdock site will be in production at one time, with another two in restoration. Reclamation will begin as soon as each mining unit has been depleted of uranium, beginning approximately two years after the start of operations. When one well field is depleted, it will be reclaimed at the same time production continues in another well field along the ore front.

5.7.6.9.2 Water Requirements for the Proposed Action Facilities

Water requirements of the CPP and other facilities are estimated to have a maximum requirement of 65 gpm. As this requirement is relatively large, it is expected that most of this water will be derived from a water supply well in the Madison formation. Some of this water may be withdrawn from the Inyan Kara formation, but if so, it will not occur in a fashion to affect any well field operations.

5.7.6.9.3 Water Usage with Reverse Osmosis and without Reverse Osmosis

Total net water use for production operations (as wellfield purge) will be in the range 20-120 gpm from the Inyan Kara. Each production site will consume between 10 and 60 gpm as well field purge. During restoration operations, water consumption will be greater from the Inyan Kara. However, net withdrawal from the Inyan Kara formation will also remain at the range of 0.5 to 3% of total restoration flow during groundwater treatment via RO method of restoration (Table 3.4-1). It is expected that the restoration activities will also be split between the two sites. Net withdrawal during these restoration operations (as well field purge) is expected to be a total of 2.5 to 15 gpm from the Inyan Kara. At each site, Dewey and Burdock, 1.25 to 7.5 gpm will be the net withdrawal during restoration operations. Net water usage from the Maddison using a (RO) unit to restore groundwater following production, approximately 167 gpm of the 500 gpm (without RO utilization; Table 3.4-2), will need to be made up with Madison aquifer water.

The actual flow rates of water leaving the Inyan Kara formation during restoration operations is expected to be in the range of 150-500 gpm. Nearly all of this water will be “made-up” by injection of water from these two sources:

Madison formation

The Madison aquifer is a source of fresh water and could potentially be utilized for the Proposed Action. Powertech (USA) would utilize the Madison Limestone, which occurs at depth throughout the entire project boundary, as a source of fresh make-up water for restoration purposes. As described below, it is very likely that the Madison aquifer can provide a source of water at the desired rate and quality sufficient for the needs of Powertech (USA) to ensure timely and successful ISL restoration goals. Depending on the exact aquifer restoration process Powertech (USA) may need to produce up to 500 gpm from the Madison aquifer. In the case of land application disposal of water during restoration, 500 gpm of make-up water will be required from the Madison aquifer. Utilizing RO, approximately one-third (or 167 gpm) of the 500 gpm will need to be made up with Madison aquifer water.

Inyan Kara formation
This is providing that make-up water is withdrawn from wells that are located far enough from operating well fields so as to not affect the cone of depression within the operating well fields.

The actual net difference between fluid produced and fluid injected must be maintained at a rate equivalent to the 0.5-3 percent bleed rates described above. With RO process used for treating well field bleed streams, permeate will be reinjected and will substantially lower the requirement for makeup waterform the Madison; such use of RO typically reduces make-up water requirements to approximately 1/3 of the water that would be required without RO (Table 3.4-2).

5.7.7 Potential Groundwater Quality Impacts from Accidents

5.7.7.1 Potential Excursions

Monitoring wells within the monitoring well ring are designed and installed to detect an excursion of leach fluids outside the well field within the aquifer exempted area. Neither historical excursions nor excursions within active ISL projects have "resulted in any significant adverse impacts to USDWs" (NMA, 2007). This demonstrates the protective capabilities of operators to detect and control excursions. Operators are mandated by permitting conditions to employ practices to protect adjacent, non-exempted aquifers. With that stated, importance is placed upon the understanding that the UIC Class III permit issued by the EPA and the uranium recovery license issued by the NRC are written and enforced to protect USDWs. The permit and license also ensures the operational processes such as: monitoring, pump tests, and maintenance of well field bleed are all geared toward protecting USDWs (NMA, 2007).

Well field imbalance is the most common cause of excursions. Imbalance can cause lixiviant to migrate outside the well field pattern toward the monitoring well ring; therefore it is crucial to characterize the groundwater within each separate well field before lixiviant is introduced into the groundwater. This well field specific groundwater data is then used to establish UCLs used for determination of properly functioning well field. One example of how an excursion is declared is "if any two excursion indicators in any monitor well exceed their respective UCLs, or a single excursion indicator exceeds its UCL by 20 percent (NMA, 2007; NUREG-1910, 2008).

Common procedure during routine sampling of monitoring wells is:

- If two of the three UCL values are exceeded in a monitor well, or if one UCL value is exceeded by 20 percent, the well will be re-sampled within 48 hours and analyzed for the excursion indicators. If the second sample does not exceed the UCLs, a third sample will be taken within 48 hours. If neither the second or third sample results exceeded the UCLs, the first sample will be considered in error.
- If the second or third sample verifies an exceedance, the well in question is placed on excursion status. Upon verification of the excursion, NRC Project Manager is notified by telephone or email within 48 hours and notified in writing within thirty (30) days.
- If an excursion is verified, the following methods of corrective action will be instituted (not necessarily in the order given) dependent upon the circumstances:
  - A preliminary investigation will be completed to determine the probable cause.
  - Extraction and/or injection rates in the vicinity of the monitor well will be adjusted as necessary to generate an effective net over-recovery, thus forming a hydraulic gradient toward the production zone.

  - Individual wells will be pumped to enhance recovery of leach fluids.
  - Injection into the production zone area adjacent to the monitor well may be suspended, while extraction continues, thus increasing the overall bleed rate and the recovery of ore zone solutions.
- In addition to the above corrective actions, sampling frequency of the monitor well on excursion status is increased to weekly. An excursion will be considered resolved when the concentrations of excursion indicators do not exceed the criteria defining an excursion for three consecutive one-week samples. Accordingly, while a real potential short-term impact, excursions during operations can be identified and controlled such that impacts are expected to be minimal.
- Impacts of excursions include the potential to contaminate groundwater outside of the well field or in aquifers above or below the production zone. However, it is noted that, in spite of excursions at virtually every operating ISL site, no significant, adverse impacts to USDWs have been documented throughout the history of ISL operations in the United States, which indicates that operators have the capability to recover errant solutions (NMA, 2007).

There are two types of excursions: vertical and horizontal. A vertical excursion is movement of solution into overlying or underlying aquifers. A horizontal excursion is a lateral movement of leach fluids outside the ore zone of the ore-body aquifer.

Maintaining injection pressures below casing and formation rupture pressures prevent the well casing from rupturing and potentially causing a vertical excursion. Well field operating pressures are monitored at the header houses via instrumentation equipped with alarms and interlocks to prevent an excursion due to excessive pressure. Consistent monitoring of well field pressures minimizes the potential for impacts to shallow and deep aquifers. MIT's have all but eliminated potential impacts from excursions to shallow aquifers (NMA, 2007).

In general, the potential environmental impacts of vertical excursions to groundwater quality in surrounding aquifers would be SMALL, if the vertical hydraulic head gradients between the production aquifer and the adjacent aquifer are small, the vertical hydraulic conductivity of the confining units is low, and the confining layers are sufficiently thick. To limit the likelihood of vertical excursions, licensees must conduct MIT to ensure that lixiviant would remain in the well and not escape into surrounding aquifers. Licensees also must conduct pre-operational pump tests to ensure adequate confinement of the production zone. In addition, licensees must develop and maintain programs to monitor above and below the ore-bearing zone to detect both vertical and horizontal excursions and flow rates, and must have operating procedures to analyze an excursion and determine how to remediate it (NUREG-1910, 2008).

During normal ISL operations, inward hydraulic gradients are maintained by production bleed such that groundwater flow is towards the production zone from the edges of the well field. This inward gradient prevents the chance of a horizontal excursion occurring. To reduce the likelihood and minimize the consequences of potential horizontal excursions, a ring of monitoring wells is installed encircling the well field pattern to enable early detection of excursions. Monitoring will be conducted for both vertical and horizontal excursions. Thus, potential *non*-radioactive contamination of groundwater beyond the production zone can have short-term impacts, but such impacts likely will be minimal and readily controllable (NMA, 2007).

5.7.7.2 Potential Spills

Types of spills that could potentially impact groundwater during operations include: a leak in a storage pond, a release of pregnant and/or barren lixiviant, a release of injection or production solutions from associated piping, spills and potential well rupture. Potential impacts of contamination to shallow aquifers and surrounding soils may result from one or a combination of these types of spills. The likelihood of spills is minimized by way of rigorous safety training, employing all necessary preventative procedures such as maintaining injection pressures below casing and formation rupture pressures, monitoring pressure in the header houses with instrumentation equipped with alarms and interlocks for early warning, and maintaining operating pressures so as to minimize the likelihood for potential impacts to shallow aquifers.

5.7.8 Potential Ecological Resource Impacts

Potential impacts to ecological resources from construction, operations, aquifer restoration and decommissioning are expected to be SMALL (NUREG-1910, 2008; BKS, 2007; ICF Jones and Stokes 2008).

Despite the relatively limited surface disturbance associated with ISL production, operations can have potential direct and indirect impacts on local wildlife populations. These potential impacts can be both short-term and long-term (persisting beyond successful completion of reclamation). However, the latter category is not expected to be substantial due to the relatively limited habitat disturbance associated with this industry and this PAA (NUREG-1910, 2008). The direct impacts of ISL production on wildlife include: injuries and mortalities caused by collisions with project-related traffic or habitat removal actions such as topsoil stripping, particularly for smaller species with limited mobility such as some rodents and herptiles; and restrictions on wildlife movement due to construction of fences (ICF Jones and Stokes, 2008). The likelihood for the impacts resulting in injury or mortality potentially would be greatest during the construction phase due to increased levels of traffic and physical disturbance during that period. Speed limits will be enforced during all construction and maintenance operations to reduce impacts to wildlife throughout the year, but particularly during the breeding season.

As indicated, most of the habitat disturbance associated with the ISL process itself will consist of scattered confined drill sites for well heads that will not result in large expanses of habitat being dramatically transformed from its original character, as is the case with other surface mining operations (NUREG-1910, 2008). Therefore, most indirect impacts would relate to the displacement of wildlife due to increased noise, traffic, or other disturbances associated with the development and operation of the project, as well as from small reductions in existing or potential cover and forage due to habitat alteration, fragmentation, or loss. Indirect impacts typically persist longer than direct impacts. However, because ISL production results in fewer large-scale habitat alterations, the need for reclamation actions that can also result in dramatic differences between pre-construction and post-construction vegetative communities is also reduced.

Multiple site visits and targeted surveys conducted over the last year, combined with existing agency databases that encompass the PAA and input from local residents, indicate that the PAA and surrounding vicinity is occupied by a wide variety of common wildlife and fish species, with only a few species of particular concern occurring in the area. The most notable species of interest is the bald eagle, which is still considered threatened at the state level. Bald eagle winter roost sites and a successful nest site were documented within the PAA during surveys conducted in 2007 and 2008. Two other species tracked by the SDNHP were confirmed or suspected to have nested in the PAA in 2008, the long-eared owl and long-billed curlew, respectively. Seven additional SDNHP species were documented in or near the PAA during baseline surveys, and one state threatened species was documented several miles northwest of the area, in extreme eastern Wyoming. However, those observations consisted of birds flying over the area, or sightings made in the surrounding perimeter. No grouse leks have been recorded within 6 miles of the PAA during agency or project-specific surveys completed in recent years.

Suitable habitat for all three nesting SDNHP species (bald eagle, long-eared owl, long-billed curlew) occurs in the PAA. However, the nature of ISL production and the presence of apparently suitable (due to low density of other nesting individuals) alternate nesting habitat throughout the PAA and perimeter combine to minimize the potential for both direct and indirect impacts for those species, and others that require similar habitats. One of those species, the long-eared owl, nested within 75 m, but largely beyond view of, an existing gravel county road, suggesting the pair has at least some level of tolerance for vehicular traffic near active nest sites. Other wildlife species of concern, such as other nesting raptors, that occur in the area may also experience direct and/or indirect impacts from increased travel and noise in the area during project construction and operation. However, the presence of potential alternate nesting and foraging habitat in the immediate vicinity, the mobility of those species, and the location of most nest sites relative to planned disturbance combine to reduce impacts to most nesting SDNHP birds as well as other species of interest.

Some vegetative communities currently present in the PAA can be difficult to reestablish through artificial plantings, and natural seeding of those species would likely take many years. However, the current habitat of greatest concern (Big Sagebrush Shrublands) occurs only in scattered stands that are relatively small and widely-spread across the PAA. Results from lek searches, breeding bird surveys, and small mammal trapping, as well as regular site visits in all seasons over the last year, strongly suggest that sage obligates other than pronghorn occur in limited numbers in the PAA, if at all. The vegetative communities (Cottonwood Gallery and Ponderosa Pine) that indicated the strongest associations between terrestrial species and habitats during baseline surveys will not be physically impacted by construction or operation of the proposed ISL Uranium project. It is possible that the potential implementation of center-pivot irrigation using well field bleed and/or restoration water may enhance nesting, brood-rearing, and/or foraging habitat for some species. Consequently, although individual animals associated with some specific habitats could be impacted by the proposed ISL operations, the relatively small percentage of projected surface disturbance within the PAA relative to its overall size, and the low density of nesting efforts relative to habitat presence in that area, suggest that their populations as a whole will experience insignificant impacts from the project. Advanced planning of construction siting and activities in concert with continued monitoring can further reduce impacts and assist with the development of mitigation options, if necessary. Potential impacts to these species and others are discussed in greater detail in the following sections.

5.7.8.1 Vegetation

Well field and production facilities will be constructed within Big Sagebrush Shrubland, Greasewood Shrubland, Ponderosa Pine Woodland, and Upland Grassland vegetation communities. Direct impacts include the short-term loss of vegetation (modification of structure, species composition, and areal extent of cover types). Indirect impacts may include the short-term and long-term increased potential for non-native species invasion, establishment, and expansion; exposure of soils to accelerated erosion; shifts in species composition or changes in vegetative density; reduction of wildlife habitat; reduction in livestock forage; and changes in visual aesthetics. An estimated 295.17 acres within the following four communities: Big Sagebrush Shrubland, Greasewood Shrubland, Ponderosa Pine Woodland, and Upland Grassland would be affected by the construction disturbance under current development plans.

Construction activities and increased soil disturbance could stimulate the introduction and spread of undesirable and invasive, non-native species within the PAA. Non-native species invasion and establishment has become and increasingly important result of previous and current disturbance in South Dakota. No threatened or endangered vegetation species were observed within the PAA; therefore, no impacts are anticipated.

Mitigation measures to lessen impacts on native vegetation and control State-designated noxious weeds are discussed in Section 5.8.6.

5.7.8.2 Wildlife and Fisheries

5.7.8.2.1 Big Game Mammals

Big game could be displaced from portions of the PAA to adjacent areas, particularly during construction of the well field and facilities, when disturbance activities would be greatest. Disturbance levels would decrease during actual extraction operations, and would consist primarily of vehicular traffic on new and existing improved and unimproved (two-track) roads throughout the PAA. Similar disturbance is already present in the area due to existing ISL exploration, ranching, and railroad operations. Pronghorn antelope would be most affected, as they are more prevalent in the area. However, no areas classified as crucial pronghorn habitat occur on or within several miles of the PAA, and this species is not as common in the general area as elsewhere within the region due to the limited presence of sagebrush in the area. Mule deer would not be substantially impacted given their somewhat limited use of these lands, the paucity of winter forage and security cover, and the availability of suitable habitat in adjacent areas. SDGFP does not consider the PAA to be within the crucial habitat range of any other big game species. Sightings of those species in that vicinity are often seasonal and less common.

5.7.8.2.1.1 Other Mammals

Medium-sized mammals (such as lagomorphs, canids, and badgers) may be temporarily displaced to other habitats during the initial ISL production activities. Direct losses of some small mammal species (e.g., voles, ground squirrels, mice) may be higher than for other wildlife due to their more limited mobility and likelihood that they would retreat into burrows when disturbed, and thus be potentially impacted by topsoil scraping or staging activities. However, given the limited area expected to be disturbed by the project, such impacts would not be expected to result in major changes or reductions in mammalian populations for small or medium-sized animals. "Displaced species may re-colonize in adjacent, undisturbed areas or return to their previously occupied habitats after construction ends and suitable habitats are reestablished" (NUREG-1910, 2000). Few bats were recorded in the area despite extra efforts to observe them during the baseline surveys. Those that were seen were near water bodies near treed habitats which are not currently scheduled for disturbance. The mammalian species known to be, or potentially, present in the PAA have shown an ability to adapt to human disturbance in varying degrees, as evidenced by their continued presence in other mining, industrial and residential areas of similar, or greater, disturbance levels elsewhere in the region. Additionally, small mammal species in the area have a high reproductive potential and tend to re-occupy and adapt to altered and/or reclaimed areas quickly.

5.7.8.2.1.2 Upland Game Birds

ISL production in the PAA would potentially impact the foraging and nesting habitat of mourning doves, though such disturbance is not expected to have any marked impacts on this species. No woody corridors will be disturbed by the proposed activities, and additional trees are present in the cottonwood gallery along the Cheyenne River, located approximately 2 miles south of the PAA, where production is not projected to occur in the near future. Additionally, doves are not restricted to treed habitats, nor are they subject to any special mitigation measures for habitat loss.

Annual monitoring surveys conducted by SDGFP biologists and a year-round baseline study for the project have demonstrated that sage-grouse do not currently inhabit that area, and have not for many years. As described previously, those surveys encompassed the entire PAA (including the September 2008 configuration) and the vast majority of its 2.0 km (1.2 mi) perimeter, particularly as part of this baseline project. The nearest known sage-grouse lek is approximately 6.0 miles north of the PAA (SDGFP records). Given the lack of sage-grouse observations in the area, and the scattered stands of marginal quality sage-grouse habitat, the proposed project will not result in negative impacts to existing or potential sage-grouse leks, or important sagebrush habitats.

5.7.8.2.1.3 Other Birds

The project could impact nine avian species tracked by SDNHP that are known to, or could potentially occur as seasonal or year-round residents. Direct impacts could include injury or mortality due to encounters with vehicles or heavy equipment during construction or maintenance operations. Indirect impacts could include habitat loss or fragmentation, and increased noise and activity that may temporarily deter use of the area by some species. Surface disturbance would be relatively minimal and could be greatest during construction. Enforced speed limits and use of common right-of-way corridors will reduce impacts to wildlife throughout the year, particularly during the breeding season.

5.7.8.2.1.4 Raptors

ISL production in the PAA would not impact regional raptor populations, though individual birds or pairs may be affected. Production activity could cause raptors to abandon nest sites proximate to disturbance, particularly if activities encroach on active nests during a given breeding season. Within the current mine plan there are no planned activities that would encroach on identified raptor nests.

Other potential direct impacts would be injury or mortality due to collisions with mine-related vehicular traffic. Construction activities that occur within or near active raptor territories could also cause indirect impacts such as reduction or avoidance of foraging habitats for nesting birds. However, surface disturbance will only occur in a small percentage of the overall PAA, and the low density of nesting raptors relative to the apparent availability of suitable habitat suggests that alternate nesting habitat is available for all known nesting raptor species in the PAA.

Eight intact raptor nests were documented within the project survey area (PAA and 2.0 km perimeter) during 2008; the mid-July 2007 start date for this project precluded nesting data from being collected last year. Six of the eight nest sites are within the proposed PAA, with the remaining two located in the one-mile perimeter. USFWS guidelines recommend a non-disturbance buffer of 0.25 to 1.0 mile around active raptor nests for species known to nest, or suspected of nesting, in the PAA (USFWS, 1998). Buffer recommendations are lowest for the two owl species in the area, as they are typically more tolerant of human activities near active nest sites. The bald eagle has the greatest buffer distance around active nests, while a 0.5-mile buffer is recommended for red-tailed hawks and merlins. Nests of most other raptor species, including all others observed, but not documented nesting, in the proposed action area are typically buffered by a radius of 0.25 to 0.50 mile.

Except for the bald eagle, the same species that nest in the PAA are known to regularly nest and fledge young at or near other surface mines throughout the region, including ISL projects. Those efforts have succeeded due to a combination of raptors becoming acclimated to the relatively consistent levels of disturbance and gradual encroachment of mine operations, and successfully executed state-of-the-art mitigation techniques to maintain viable raptor territories and protect nest productivity. Some individuals nest on active mine facilities themselves, including both great horned owls and red-tailed hawks. The lack of bald eagle examples is more likely related to the general absence of nesting bald eagles in the vicinity, rather than an increased sensitivity to mine activities. Bald eagles will be discussed further in the T&E section later in this document. Due to the paucity of river cliffs in the PAA, falcons and other raptors known to nest in that habitat are not as abundant as those that nest in trees or even on the ground.

Based on the location of known nest sites relative to future construction sites, no raptor nests will be physically disturbed by the project during either construction or operations. Additionally, Powertech (USA) has incorporated the baseline wildlife information into their planning process and sited all plant facilities (areas of greatest sustained future disturbance) outside the recommended buffer zone for all raptor nests in the PAA, including the bald eagle nest site. Some new infrastructure will be located within the suggested buffer areas. However, pipelines will be buried, and new overhead power lines will be constructed using designs and specifications to reduce injuries and mortalities on overhead power lines. Center-pivot structures can be put into place prior to the nesting season, and run automatically with little human contact once they are turned on. Additionally, new roads, power lines, and pipelines will be constructed in the same corridors to the extent possible to reduce overall disturbance, and in existing corridors when available to minimize new surface disturbance.

5.7.8.2.1.5 Waterfowl and Shorebirds

Construction and operation of the proposed project would have a negligible effect on migrating and breeding waterfowl and shorebirds. Existing habitat is limited and seasonally available in the PAA, so it does not currently support large groups or populations of these species. Multiple approaches are being considered to minimize impacts to wildlife that may be associated with the operation of ponds. Any new treated water sources could enhance current habitat conditions for these species, though such effects may be temporary in nature. Water quality within the ponds likely will not have any significant adverse impacts upon avian species because it is basically fresh water.

5.7.8.2.1.6 Reptiles, Amphibians, and Fish

As with waterfowl, potential habitat for aquatic and semi-aquatic amphibians and reptiles, is limited within the proposed PAA, and occurs primarily along Beaver Creek in the western portion of the area. Other water bodies are ephemeral, and thus offer only short-term habitat. Activities associated with the project are not expected to disturb existing surface water or alter the topography in the area. Those species residing in rocky outcrops located in potential disturbance areas could be impacted by construction and maintenance operations. However, few non-aquatic herptile species were observed in the PAA and surrounding perimeter. Any impacts that occur could affect individuals, but would not likely impact the population as a whole.

5.7.8.2.1.7 Fish and Macroinvertebrates

The planned locations for new facilities and infrastructure do not overlap any perennial aquatic features, no loss of aquatic habitat would occur as the result of their construction. The risk of impaired water quality will be reduced or avoided through project siting, and implementation of standard construction erosion and sediment control measures. The location of production facilities (processing plants, pipelines, new roads and power lines), as well as the proposed land application sites (center pivot irrigation sites) will avoid direct impacts to perennial streams.

Due to the arid climate and proposed location of new mine facilities, operation of the well fields is not expected to alter aquatic habitat or water quality in perennial streams. No surface water will be diverted for use in the operation, and no process water will be discharged into aquatic habitat.

Pass creek provides only seasonal drainage and does not support fish or significant amphibian habitat. The proposed processing sites and land application sites are intentionally located away from Beaver Creek, Pass Creek and other aquatic habitat, the primary aquatic habitat in the project vicinity. Therefore, aquatic habitat will not be directly affected by the well field operations or land application sites.

5.7.8.3 Threatened and Endangered, or Candidate Species and Species Tracked by SDNHP

5.7.8.3.1 Federally Listed Species

As described in the preceding sections of this document, no federally listed vertebrate species were documented in the project survey area (current PAA and 2.0 km perimeter) during the year-long survey period, or during previous targeted surveys conducted for the original claims (TVA 1979). Additionally, the USFWS has issued a block clearance for black-footed ferrets in all black-tailed prairie dog colonies in South Dakota except northern Custer County, and in the entire neighboring state of Wyoming. That clearance indicates that ferrets do not currently, and are not expected to, occupy the PAA. Only one small black-tailed prairie dog colony was present in the PAA itself during the 2007-2008 baseline surveys, and local landowners are actively working to remove the animals from their lands. Consequently, the proposed project will have no direct, indirect, or cumulative effects on black-footed ferrets.

5.7.8.3.2 State Listed Species

ISL within the project is not likely to adversely affect, bald eagles, the only state listed species known to inhabit the PAA. Bald eagles were documented at winter roosts and an active nest within the PAA for this project. However, most roost sites and the lone nest site are at least 1.0 mile from the nearest planned facility associated with this project. Additionally, no more than two or three bald eagles were observed during any given winter survey. This is despite the numerous available (and unoccupied) mature trees along Beaver Creek, Pass Creek, and the pine breaks located in and near the PAA. Three proposed land application sites (center pivot irrigation systems) would currently fall within the one-mile buffer of the bald eagle nest. However, those systems are typically automated, and the minimal disturbance associated with potential maintenance of those systems should not be significant enough to impact nesting or roosting bald eagles along Beaver Creek.

Direct impacts to bald eagles could include the potential for injury or mortality to individual birds foraging in the PAA due to electrocutions on new overhead power lines. Although not expected, disturbance activities near an active nest could result in abandonment and, thus, the loss of eggs or young. The increased human presence and noise associated with construction activities, if conducted while eagles are wintering within the area, could displace individual eagles from using the area during that period.

Given the low number of wintering and nesting bald eagles in the PAA, potential impacts of the proposed project would be limited to individuals rather than a large segment of the population. The use of existing or overlapping right-of-way corridors, along with best management practices will minimize potential direct impacts associated with overhead power lines. If necessary, the majority of other potential impacts could be mitigated if construction activities were conducted outside the breeding season and/or winter roosting months, or outside the daily roosting period, should eagles be present within one mile of construction. Any bald eagles that might roost or nest in the area once the mine is operational would be doing so in spite of continuous and on-going human disturbance, indicating a tolerance for such activities.

Indirect impacts as a result of noise and human presence associated from mine related operations could include area avoidance by avian species. Potential winter foraging habitat could be further fragmented by linear disturbances such as overhead power lines and new roads associated with the project. Given the size of the proposed project, those disturbances would occur within narrow corridors over relatively short distances. Nevertheless, the use of common right-of-way corridors to consolidate new infrastructure will reduce these potential indirect impacts.

The only other state-listed species recorded in the general area was the river otter. An otter carcass was discovered lodged in debris in the stream channel at fisheries sampling station BVC04 in mid-April 2008. That site is approximately 12 river miles upstream from the PAA boundary in eastern Wyoming. The carcass had washed away by the July 2008 fisheries sampling session. The monthly sampling at BVC04 during the monitoring period, confirmed no additional observations of otters. Likewise, no evidence of otters was report by biologists along any drainage elsewhere in the PAA (proposed permit area and 2.0 km perimeter) during the year-long baseline survey period (mid-July 2007 through early August 2008). Given the fact that no stream channels will be physically impacted in the PAA, the lack of otter sightings or sign in the PAA itself, and the stringent water processing and water quality monitoring that will occur, this project is not likely to directly or indirectly impact river otters.

5.7.8.3.3 Species Tracked by SDNHP

Ten terrestrial species tracked by the SDNHP were recorded during baseline surveys for the uranium project, including the bald eagle. Seven of the ten were observed within the PAA, and three were seen in the 2.0 km perimeter. One additional species, the plains topminnow, was observed in Beaver Creek and the Cheyenne River, at least 1.0 mile outside the PAA. Three SDNHP species are known or suspected to have nested in the PAA in 2008. However, two of the three nest sites are at least 1.0 mile from the nearest planned new facility, and all three were closer to existing disturbances in 2008 than they would be to new activities outside those existing areas.

The seven SDNHP species recorded in or flying over the PAA could potentially experience the same type of direct and/or indirect impacts from construction and operation of the Proposed Action as those described previously for other species: e.g., injury, mortality, avoidance, displacement and increased competition for resources. Those potential impacts will be minimized by the timing, extent, and duration of the proposed activities. Enforced speed limits during all phases of the project will further reduce potential impacts to wildlife throughout the year, particularly during the breeding season. Once facilities and infrastructure are in place, and hunting pressures decrease, animals remaining in the PAA could demonstrate an acclimation to those disturbances.

5.7.9 Potential Air Quality Impacts

5.7.9.1 Potential Air Quality Impacts of Construction

ISL process facilities do not typically affect air quality drastically (NUREG-1910, 2008). The impacts due to construction are classified as SMALL if 1) the gaseous emissions are within regulatory limits;

2) the air quality in the region of influence is in compliance with the National Ambient Air Quality Standards (NAAQS); and 3) the facility is not classified as a major source according to the New Source Review or operating permit programs. Because of the isolated location (13 miles northwest of Edgemont) and the atmospheric conditions of the PAA, the cumulative air quality impacts will be negligible.

The construction phase of ISL projects generally produces non-radiological gaseous emissions including fugitive dust and combustion emissions. Diesel emissions from construction equipment comprise the majority of the combustion emissions and are considered to be small, short-term effects.

Potential air quality impacts during construction activities at the project will include emissions from heavy equipment, vehicle and drill rig exhaust, dust from traffic, and dust from disturbing soil during drilling and ground-clearing activities. Mobile sources of emissions will be diesel engines on the drill rigs and diesel water trucks. All vehicles on-site will meet Environmental Protection Agency (EPA) and Department of Transportation (DOT) vehicle emission standards.

The greatest amount of dust will be generated from vehicular traffic on the unpaved roads; therefore, speed limits will be imposed for employee vehicles and transport trucks in order to mitigate the amount of dust generated from unpaved roads. Employee car pooling will be encouraged, which will keep the vehicular traffic at a minimum. Temporarily disturbed areas will be reseeded and restored as soon as possible to minimize erosion of soil and fugitive dust emissions.

5.7.9.2 Potential Air Quality Impacts of Operation

As a general matter, ISL operations are not major point source emitters and are not expected to be classified as major sources of emissions (NUREG-1910, 2008). Emissions may be introduced during the operation phase of an ISL project including the release of pressurized vapor from well field pipelines. Other additional possible emissions include those that may be emitted during resin transfer or elution. Naturally occurring radon gas may also be released when the well pipeline system is vented. Non-radiological emissions from pipeline system venting, resin transfer, and elution are expected to have a minimal impact on air quality at the site due to the low volume of effluent produced and the rapid dispersion of the emissions (NUREG-1910, 2008).

Due to the utilization of the pressurized down-flow IX columns there are virtually no releases of radon to the atmosphere. Indeed, none of the IX process circuit is open to the atmosphere except for short periods during transfer of resin. During resin transfer, fans vent radon released from the resin transfer process from the CPP to the outside atmosphere.

Yellowcake drying operations can also produce gaseous effluents. The project yellowcake will be dried at approximately 450 °F in a rotary vacuum drying process. The impacts related to yellowcake drying will be to be SMALL because vacuum driers basically release no gaseous effluents other than water vapor (NUREG-1910, 2008).

Fugitive dust and emissions from on-site traffic associated with operations and maintenance will also be expected, but will amount to less than was produced during construction of the facilities at the site, so impacts are expected to be SMALL (NUREG-1910, 2008).

Impacts during aquifer restoration and decommissioning phases to air quality are expected to be similar (SMALL) to impacts during operations (NUREG-1910, 2008).

Section 5.8.7 discusses the mitigation measures for air quality impacts.

5.7.10 Potential Noise Impacts

5.7.10.1 Potential Noise Impacts of Construction

Because of the remote location of the project site and lack of sensitive receptors, noise impacts are not expected to increase beyond ambient levels due to plant operations. Likewise, no detrimental off-site noise impacts are anticipated due to the increase in commuter and truck traffic volumes or from construction. Noise levels generated during operation of the ISL project are not expected to result in any significant impacts to violate any noise standards. Open rangeland and pastureland are the primary land uses within the PAA and the surrounding 2.0-km area.

Outdoor noise levels at the nearest off-site receptors will be well within the 55-dBA daytime guideline, to protect against activity interference and annoyance (EPA, 1978). Noise levels during mine unit construction should cause no off-site impacts, since the PAA is not in close proximity to off-site receptors and will occur only during daylight hours.

Section 5.8.8 discusses the mitigation measures for noise impacts.

5.7.10.2 Potential Noise Impacts of Operations

Because of the remote location and lack sensitive receptors noise potential impacts are not expected to increase beyond ambient levels due to plant operations. Likewise, no detrimental off-site noise impacts are anticipated due to the increase in commuter and truck traffic volumes or from construction. Noise levels generated during operation and reclamation of the project are not expected to result in any significant potential impacts that would violate any noise standards. Exposure limits during operations will meet OSHA current permissible exposure limit for workplace noise (29 CFR 1910.95).

Outdoor noise levels at the nearest off-site receptors will be well within the 55-dBA daytime guideline, to protect against activity interference and annoyance (EPA, 1978). Noise levels during process operation and reclamation should cause no off-site impacts, since the PAA is not in close proximity to off-site receptors and will occur only during daylight hours.

Section 5.8.8 discusses the mitigation measures for noise impacts.

5.7.11 Potential Historic and Cultural Resources Impacts

A Level III Cultural Resources Evaluation was conducted in the PAA (Appendix 5.7-B). Personnel from the Archaeology Laboratory, Augustana College (Augustana), Sioux Falls, South Dakota, conducted on-the-ground field investigations between April 17 and August 3, 2007.

Augustana documented 161 previously unrecorded archaeological sites and revisited 29 previously recorded sites during the current investigation. Expansion of site boundaries during the 2007 survey resulted in a number of previously recorded sites being combined into a single, larger site. Twenty-eight previously recorded sites were not relocated during the current investigation. Excepting a small foundation, the non relocated sites were previously documented as either prehistoric isolated finds or diffuse prehistoric artifact scatters.

Prehistoric sites account for approximately 87 percent of the total number of sites recorded. Historic sites comprise approximately 5 percent of total sites recorded, while multi-component sites (prehistoric/historic) comprise the remaining 8 percent. Ten of the sites documented have only prehistoric and historic components.

The small number of Euro-American sites documented was not unanticipated given the peripheral nature of the PAA in relation to the Black Hills proper. The disparity existing between the number of historic and prehistoric sites observed in the PAA is also not unexpected; however, the sheer volume of sites documented in the area is noteworthy. The land evaluated as part of the Level III cultural resources evaluation has an average site density of approximately 1 site per 8.1 acres. Even greater site densities were reported in 2000 during the investigation of immediately adjacent land parcels for the Dacotah Cement/BLM land exchange (Winham et al., 2001). This indicates that the proposed Permit Area is not unique, in regards to the number of documented sites, and is typical of the periphery of the Black Hills.

As construction takes place any previously undetected historical or cultural resources will be reported to the proper agency. The site will be evaluated and released by the proper agency before construction continues within the specific area. The phased approach that Powertech (USA) proposes will increase the likelihood of safeguarding historical and/or cultural resources. Another example of phasing is a license condition that requires cessation of any site activities and the conduct of a cultural resources inventory if previously undetected historic or cultural properties are discovered during the development and construction of wellfields. Thus, “phasing” is an essential and integral component of *all aspects* of ISL uranium recovery projects (NMA, 2007).

Powertech (USA) has executed a Memorandum of Agreement, (MOA), attached as Appendix 5.7-C to this document with the State Archeologist to ensure to preservation of any historical sites that may be present within the PAA. The MOA outlines all actions needed to ensure no significant historic, cultural, or archeological resources will be damaged during production activates.

Section 5.8.9 discusses the mitigation measures for historic and cultural resources impacts.

5.7.12 Potential Visual/Scenic Resources Impacts

Potential short term impacts to the visual resources produced during construction will come from the addition of access roads, electrical distribution lines, header houses as well as drilling. Temporary impacted areas will be reclaimed upon completion of construction and debris created during construction will be removed as soon as possible to limit the areal extent affected during construction. The sources of potential long-term impacts to the visual resources will be the presence of the central plant, wellhead covers, access roads, a pipeline, holding ponds, and several ancillary buildings. These potential long-term visual impacts will remain present until the completion of restoration and reclamation, which will efface the presence of the visual impacts associated with the proposed action.

The proposed action will result in temporary, minor impacts to visual and scenic resources. The project will maintain the visual resource classification of the area. According to NUREG-1569, if the visual resource evaluation rating is 19 or less, no further evaluation is required. Based on the visual resource inventory conducted in June 2008, the total score of the two Scenic Quality Rating Units within the Proposed License Area were 11 and 13; therefore, no further evaluation of the existing scenic resources or future changes to the scenic resources of the area due to the proposed action will be required.

To minimize potential impacts to visual and scenic resources, building materials and paint will be selected that complement the natural environment, according to BLM guidelines. Construction and placement of structures will take into consideration the topography in order to conceal wellheads, plant facilities, and roads from public vantage points. In order to mitigate the visual impacts of roads constructed, the topography that the road follows as well as the area of disturbance will be considered.

Impacts during aquifer restoration and decommissioning phases to visual resources are expected to be the same or less (SMALL) to impacts during operations (NUREG-1910, 2008).

Section 5.8.10 discusses the mitigation measures for visual/scenic resources impacts.

5.7.13 Potential Socioeconomic Impacts

Although a proposed facility size and production level can vary, the peak annual employment at an ISL facility range up to about 200 people, including construction (Freeman and Stover, 1999; NUREG-1508, 1997; Energy Metals Corporation, U.S., 2007) as stated in NUREG-1910. In general the number people associated with an ISL facility workforce could be as many as 500 (i.e., 200 workers times 2.5 persons per household) (NUREG-1910, 2008). The following section highlights potential socioeconomic impacts of the proposed project to Custer and Fall River Counties. A cost-benefit analysis for the proposed action is presented in Section 7.0. Overall, potential socioeconomic impacts from ISL facilities in the proposed project region would range from SMALL to MODERATE (NUREG-1910, 2008).

5.7.13.1 Construction

Assuming a peak workforce of about 86 payroll employees, the influx of workers is expected to result in a small to moderate impact in Custer and Fall River Counties because of the short duration of construction phase (18-24 months) and the small size of the workforce compared to the regional labor pool of 9,202 people working full and/or part-time jobs (SD-REAP, 2008). The impacts of worker influx will be mitigated by preferentially sourcing the labor force from the within the surrounding region.

The potential direct, indirect and induced effects on Custer and Fall River Counties' employment are shown on Table 5.7-2. The direct employment effects refer to the employment directly generated by the project. For the initial construction phase beginning in year one, the IMPLAN model estimated 171 additional non-payroll workers hired in Custer and Fall River Counties based on the estimated 86 payroll workers engaged directly in construction activities and the $45.8 million in non-payroll capital expenditures incurred by the project per year.

Table 5.7-2 Employment Effects of the Project in Custer and Fall River Counties

Years	Employment			
	Direct	**Indirect**	**Induced**	**Total**
1-2	86	45	126	257
3-9	84	36	35	155
10-17	18	3	3	24

Potential indirect effects pertain to the inter-industry effects from the direct effects and could include increased labor demands, goods and services required to support the ISL project (e.g. retail and restaurant staff). In addition, new workers living within Custer and Fall River Counties would spend their income locally, which would induce additional income and employment. The sum of potential direct, indirect and induced effects represents the total potential employment impacts of the project. These results indicate that the project has the potential to create a total of 257 jobs during the construction stage.

5.7.13.2 Operations Workforce

Assuming an operation phase workforce of about 84, the influx of workers is expected to result in a small to moderate impact in Custer and Fall River Counties, because of the small size of the workforce compared to the regional labor pool of 9,202 people working full and/or part-time jobs (SD-REAP, 2008). The impacts of worker influx will be mitigated by preferentially sourcing the labor force from the within the surrounding region.

For the operation phase of the project, the IMPLAN model estimated 71 additional non-payroll workers will be hired in Custer and Fall River Counties based on the estimated 84 payroll workers engaged directly in the operation activities and the $21.2 million in non-payroll capital expenditures incurred by the project per year. The economic impacts of these newly created 155 jobs during the operation phase of the project are not limited to Custer and Fall River Counties, but will likely affect the surrounding Counties of Weston, Niobrara, and Pennington because of increased commerce and capital exchange within the region.

5.7.13.3 Potential Effects to Housing

Because of the project's close proximity to the more populated communities of Custer City and Hot Springs, South Dakota and Newcastle, Wyoming with a combined population greater than 9,000 people, it can be assumed that much of the workforce would come from these localities. The remaining workforce would likely relocate from the surrounding area (e.g., South Dakota, Nebraska and Wyoming). The IMPLAN model results show that during the two year constructional stage, the Proposed Action has the potential to sustain the creation of 257 new jobs for two years. During the following 7 year operation stage the project has the potential to sustain the creation 155 jobs for seven years, and 24 jobs over the final seven years.

In the unlikely event that the entire direct payroll and non-payroll workforce relocated to Custer and Fall River counties, the population increase for the three stages of operations would be 619, 374 and 58, based on the average family size in South Dakota of 2.41 as of 2006. This increase in population would account for an increase of 6.9 percent (total population 15248) in the total population of Custer and Fall River counties. This is a very conservative estimate because it is likely that a large percentage of the workforce for operation and reclamation will be sourced from the existing workforce, thereby reducing the total population increase substantially. The impacts associated with an increase in population are expected to be dispersed because of the remoteness of the project site and the phased nature of construction, operation and reclamation. While this is a moderate increase in the overall percentage of the local population, this influx of immigration could be partially mitigated by implementing a preferential hiring scheme and using regional educational/training institutions to help train workers and to ensure that as many of the local residents are hired as possible.

5.7.13.4 Potential Effects to Services

There are several schools located within Custer and Fall River Counties. The Custer School District includes: Custer Elementary, Hermosa Elementary, Fairburn Elementary, Spring Creek Elementary, Custer Middle, and Custer High School. Total enrollment for the Custer School District is 991 students with a student to teacher ratio of 12.1 to 1. The Hot Springs School District includes: Hot Springs Elementary, Hot Springs Middle and Hot Springs High School. Total enrollment for the Hot Springs School District is 873 students with a student to teacher ratio of 12.9 to 1. The Edgemont School District includes: Edgemont Elementary, Edgemont Junior High and Edgemont High School with a total enrollment of 138 students and a student to teacher ratio of 8.8 to 1.

Families moving into the aforementioned school districts near the project site as a result of the project are not expected to strain the current school system because they presently under-capacity as shown by the combined student teacher ratio for the three school districts of 12.1:1 as compared to the State wide student teacher ratio of 13.4:1 and the national average of 15.7:1.

The costs associated with increased demand of public facilities and services are expected to be minimal. The need for additional water supply and waste disposal facilities are expected to be minimal based on adequate existing capacity. Existing emergency response and medical treatment facilities are capable of responding to any possible incident at the project site; therefore the basic services required to support the project already exist. Since the majority of the workforce will be local there are no significant changes or stresses anticipated for other public services, such as police, health care, or utilities.

5.7.13.5 Economic Impact Summary

According to the Cost-Benefit Analysis in Section 7, the most significant benefits of the Proposed Action are its potential to sustain the creation of 257 new jobs during construction, 155 jobs during operation, and 24 jobs during reclamation, all of which include the direct, indirect and induced effects on the local economies. In addition, an estimated $91.6 million during construction will be spent on non-payroll expenditures, $148.4 million during operation and 14.0 million during reclamation; and approximately $35.1 million in state and local tax revenue and $186.7 million in value added benefits are expected to be generated over the life of the Proposed Action (Table 5.7-3).

Table 5.7-3 summarizes the associated short-term and long-term cost of the Proposed Action. Impacts to the regional housing market should be minimal because of the large percentage of local workers, impacts to schools and public facilities should be negligible because of their present ability to absorb any associated regional influx, and the impact of noise and additional traffic presents little or no change compared to the no action alternative. Due to the remote location of the project Site and minimal surface disturbance, impacts to recreational activities and aesthetic values within the area should be negligible.

This CBA indicates that the construction and operation costs including capital costs of this project will result in positive economic benefits to the local and regional economy by the creation of hundreds of jobs and millions of dollars in tax revenue over the life of the project. The development the ISL project should present Custer and Fall River counties with net positive gain when compared to the no action alternative.

Table 5.7-3 Summary of Benefits and Costs for the Proposed Action

Benefits	Costs
▪ **Value Added** $186,697,204 ▪ **Tax Revenue** $35.1 million ▪ **Potential to create temporary and permanent jobs** 257 jobs over two years during construction 155 jobs over seven years during operation 24 jobs over eight years during reclamation ▪ **Increased knowledge of the local environment and natural resources**	▪ **Housing Impacts** Little or no change ▪ **Schools and Public Facilities** Negligible ▪ **Noise and Congestion** None ▪ **Impairment of Recreation and Aesthetic Values** Negligible ▪ **Land Disturbance** Minor ▪ **Groundwater Impacts** Controlled through mitigation ▪ **Radiological Impacts** Controlled through mitigation

5.7.14 Potential Environmental Justice Impacts

The U.S. Census 2000 Decennial Population program provides information about race and poverty characteristic for Census Tracts for the areas surrounding the PAA. The 2000 Census Tract data for South Dakota was used to compare the demographic data for the counties surrounding the PAA. These data were also used to determine if there was a disproportionate percentage of minorities or low-income populations that might be affected by the PAA relative to the State.

As shown in Table 5.8-4, minorities make up less than 7.0 and 11.0 percent of the total population for Custer and Fall River Counties, respectively, which is less than the state average of 12.0 percent. No concentration of minorities was identified to reside near the PAA, which is located in a rural area, while most of the minority population lives urban centers such as Custer City (Census Tract 9952) or Hot Springs (Census Tract 9942).

Census Tract information regarding median household incomes and poverty statistics for Custer and Fall River counties is only available from the decennial federal census. Median household income levels were $36,303 for Custer County and $29,631 for Fall River County compared with $35,282 for the State average. The two census tracts within Fall River County (9941 and 9942) are below the State average for median household income levels, but they are all well above the 2000 poverty level of $17,603 for a family of four, while the average of Custer Counties two census tracts was well above the State's average. The poverty rate in Custer County was 9.4 percent and 13.6 percent in Fall River County. Compared to the state-wide average of 13.2 percent, Fall River's poverty rate is only slightly higher, while Custer County is well below the state-wide; therefore, there is not a disproportionate concentration of low-income populations within the study area compared to the State as a whole (USCB, 2000).

Table 5.7-4 Race and Poverty Characteristics for Areas Surrounding the Proposed Action

	Custer County CT - 9951	Custer County CT- 9952	Custer County	Fall River County CT - 9941	Fall River County CT - 9942	Fall River County	State of South Dakota
White, non-Hispanic Population	95.0	90.8	93.4	92.4	87.5	89.3	88.0
Total Racial Minority Population	5.0	9.2	6.6	7.6	12.5	10.7	12.0
White, Hispanic Population	1.4	1.7	1.5	1.3	2.0	1.7	1.4
Native American Population	2.1	4.8	3.1	4.1	7.2	6.1	8.3
Median Household Income in 1999 dollars	$37,083	$34,837	$36,303	$31,759	$27,337	$29,631	$35,282
Percent Below Poverty Level	10.0	8.4	9.4	13.3	13.8	13.6	13.2
Total Population	4,517	2,758	7,275	2,767	4,686	7,453	754,844

It is possible that some low-income individuals or minorities may reside within the study area, but not disproportionately compared with the state-wide averages. Also, since the proposed project is not expected to generate any significant adverse environmental impacts to the area's natural resources, there will not be any disproportionate environmental consequences to minority groups or low income populations.

5.7.15 Potential Public and Occupational Health Impacts

Powertech (USA) is required to implement radiological monitoring and safety programs that comply with 10 CFR Part 20 requirements to protect the health and safety of workers and the public. Powertech (USA) will employ the principles of ALARA at all times concerning activities covered under the NRC license. NRC will periodically inspect Powertech (USA) programs to ensure compliance (NUREG-1910, 2008).

5.7.15.1 Potential Nonradiological Impacts

The area within an 80-kilometer (50-mile) radius surrounding the PAA includes portions of counties within western South Dakota, eastern Wyoming, and northeastern Nebraska. The nearest resident is located approximately 1.4 km from the center of the proposed project in the south sector (Figure 5.7-1).

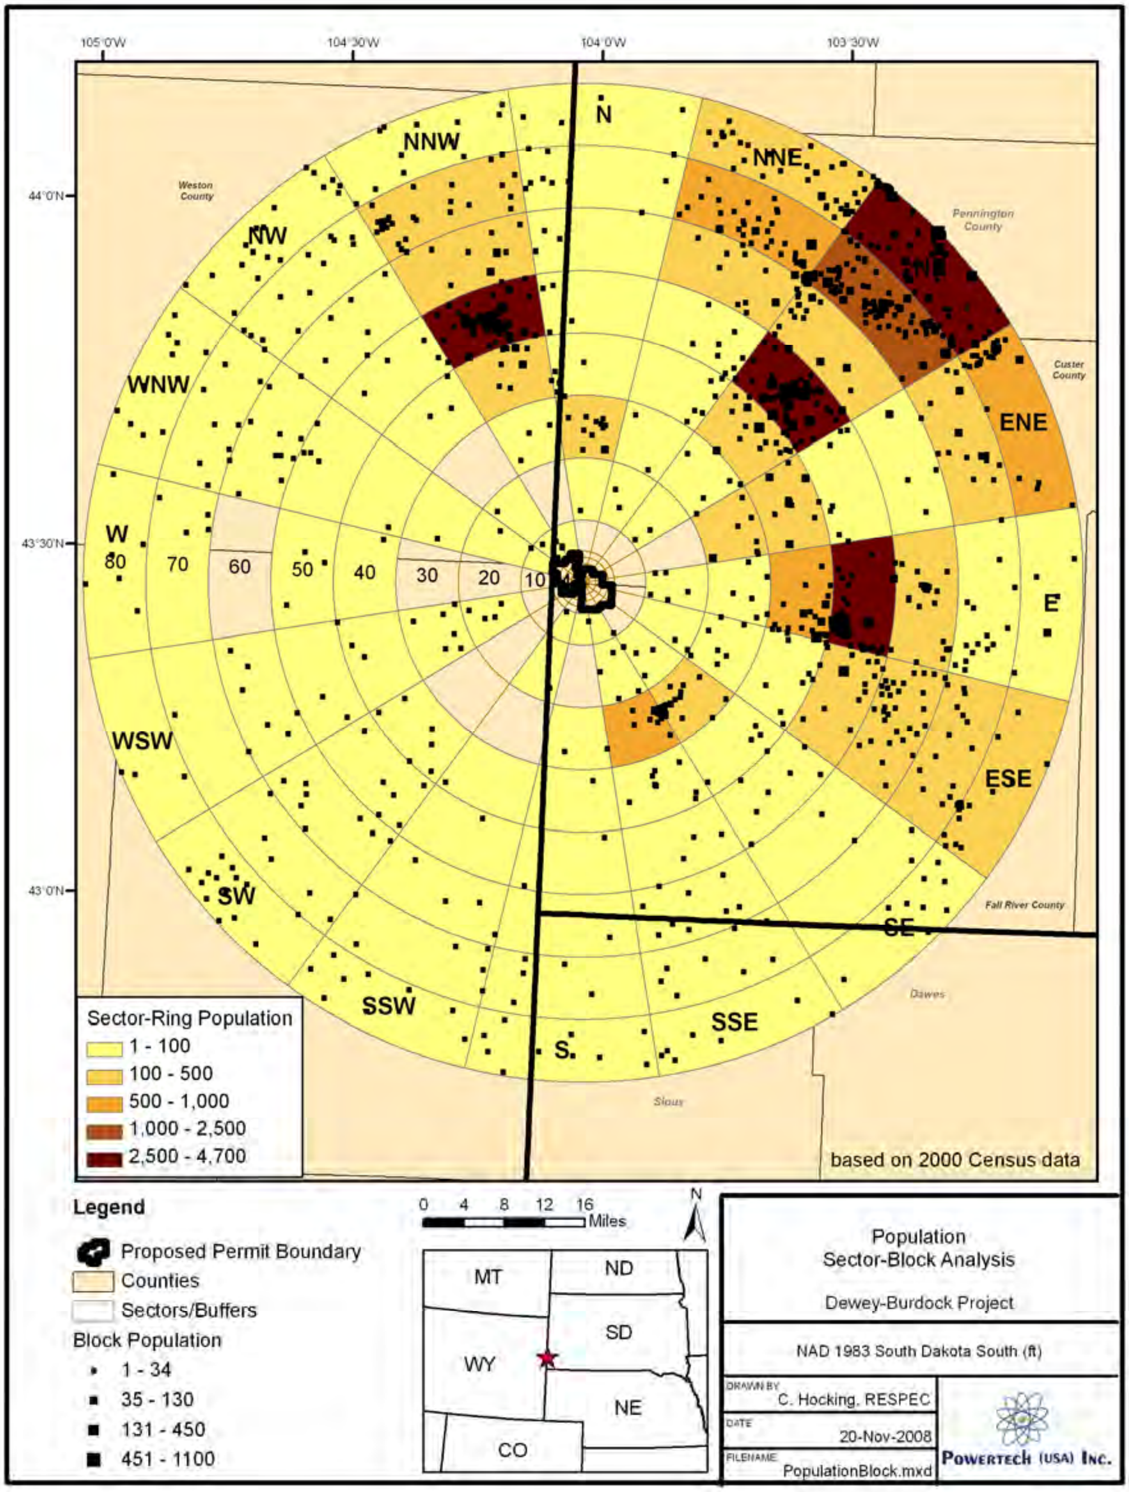

Figure 5.7-1 Population Sector Block Analysis

5.7.15.1.1 Potential Chemical Impacts

In general, most ISL facilities utilize chemicals during the extraction process and during restoration of groundwater quality. Bulk chemicals will be stored on-site in areas at a distance from the processing facilities that will pose no significant hazard to the public or workers' health and safety. Powertech (USA) will have strict standard operating procedures regarding receiving, storing, handling, and disposal of chemicals to ensure the safety of the public and workers. Industrial safety aspects associated with the use of chemicals will be regulated by several agencies including the EPA, SD DENR and OSHA.

Process-related chemicals stored on-site will include anyhydrous ammonia, carbon dioxide, hydrogen peroxide, oxygen, sodium carbonate and sodium chloride, barium chloride, and sulfuric acid and hydrochloric acid. Risk assessments completed by the NRC in NUREG-6733 for ISL facilities identified anhydrous ammonia and bulk acid (sulfuric and hydrochloric) storage as the most chemicals with the greatest potential for impacts to chemical safety.

Potential health and safety impacts could result from an accidental release of these chemicals. Releases of these chemicals at levels greater than the reportable quantity level under the Community Right to Know Act (40 CFR 355) will be reported to the National Response Center, EPA, SDDENR, and NRC. Specific quantities or uses of chemicals that require certain controls, procedures, or safety measures are defined by statutes:

- 29 CFR Part 1910.119 and 1910.120
- 40 CFR Part 68, 302.4, and 355

Compliance with these necessary requirements will reduce the likelihood of a release. Offsite impacts would be SMALL, while impacts to workers involved in response clean up could be MODERATE. Any such impacts will be mitigated by implementing procedures and training requirements (NUREG-1910, 2008).

Restoration activities will at times overlap with some operational activities such as operation of well fields, wastewater treatment, and disposal. The occupational health and safety impacts are expected to be less than operational impacts due to the absence of some operational activity, such as yellowcake drying operations and IX. Therefore, aquifer restoration is expected to have a SMALL impact to workers and the general public (NUREG-1910, 2008).

5.7.15.2 Potential Radiological Impacts

Potential radiological impacts:

- Well fields
- Processing facilities
- Unplanned release
- Land application

Using the required RESRAD and MILDOS models, the potential radiological impacts were assessed.

5.7.15.2.1 Exposure Pathways

The potential exposure pathways from all potential sources on-site are presented on Figure 5.7-2. Atmospheric Rn-222 is one pathway for impacts on human and environmental media. Radon-222 has a relatively short half-life (3.2 days) and its decay products are short lived, alpha emitting, nongaseous radionuclides. These decay products have the potential for radiological impacts to human health and the environment. As Figure 5.7-2 shows, all potential exposure pathways, with the possible exception of absorption, can be important depending on the environmental media impacted. All of the pathways related to air emissions of radionuclides are evaluated by MILDOS-AREA.

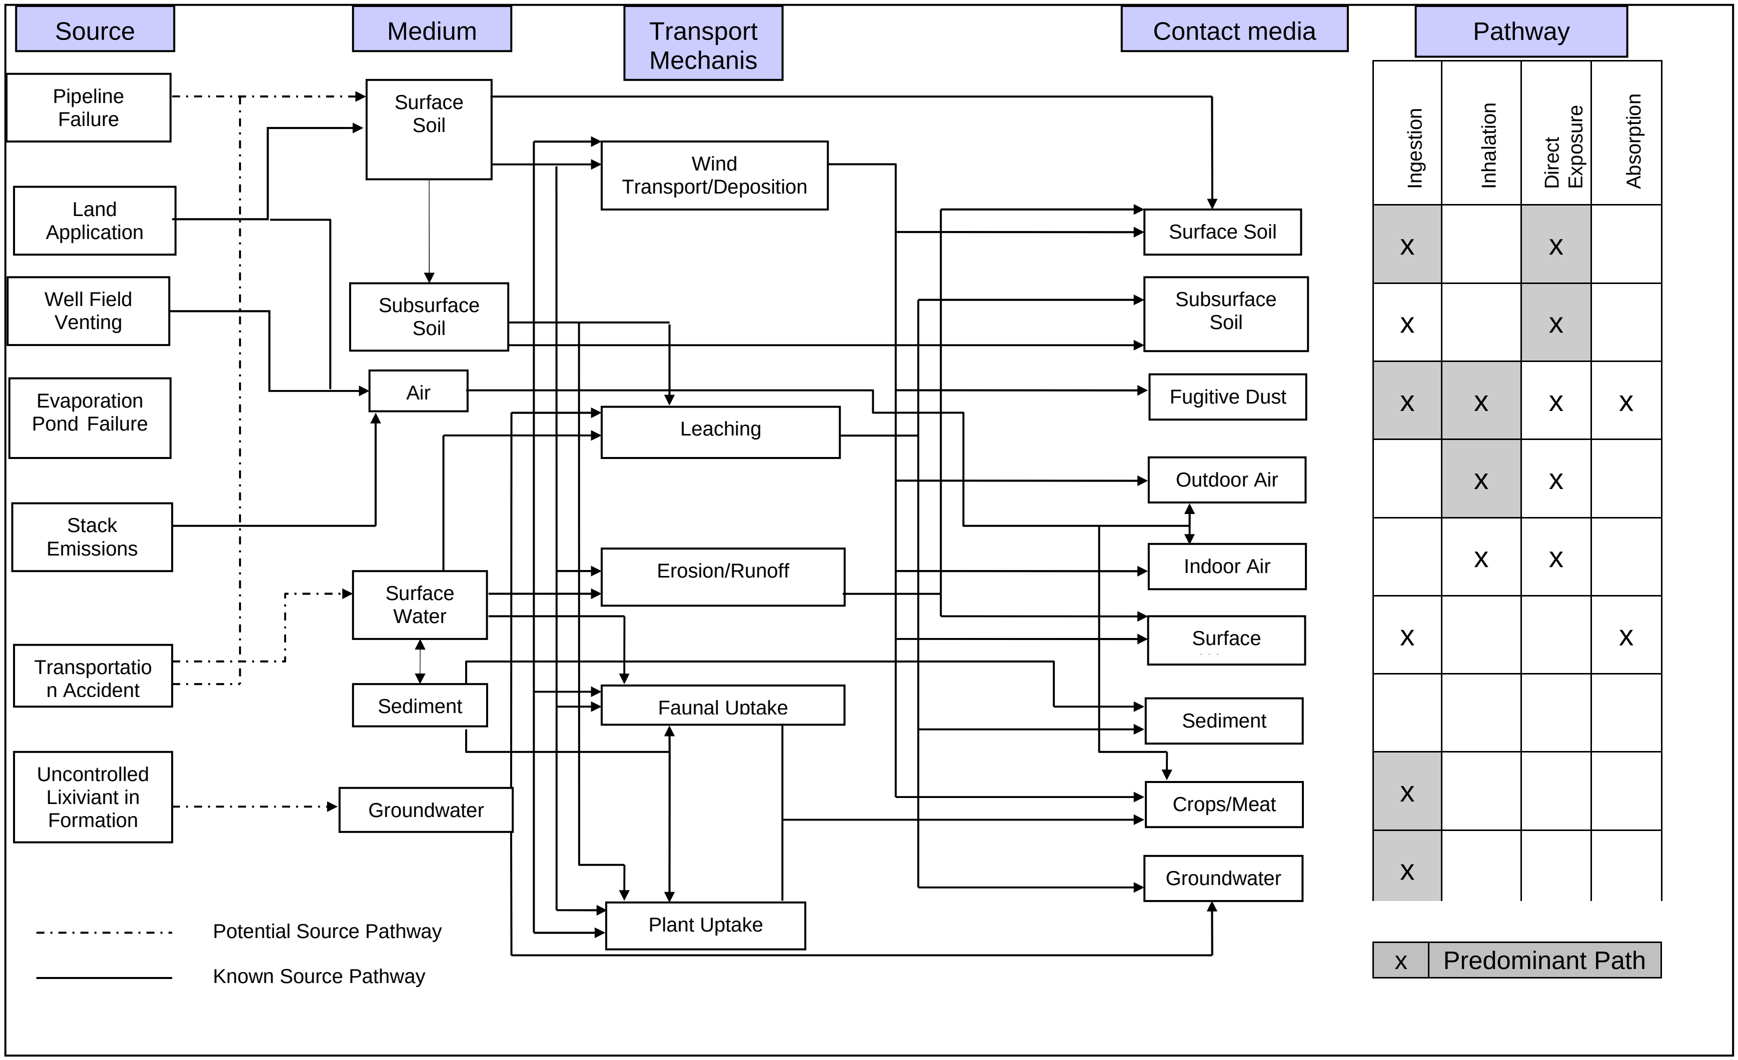

Figure 5.7-2 Human Exposure Pathways

5.7.15.2.2 Exposures from Water Pathways

The leach fluids in the ore zone will be controlled and monitored to ensure that there is no migration to surface waters or adjacent non-exempt USDWs.

Two methods of waste disposal at the facility are being considered: Either treatment to remove radium and subsequent injection in a Class I or V disposal well, or by the same treatment followed by land application.

The uranium IX, precipitation, drying and packaging facilities will be located on curbed concrete pads to prevent any liquids from entering the environment. Solutions used to wash down equipment drain to a sump and are either pumped back into the processing circuit or to wastewater treatment and disposal. The pads will be of sufficient size to contain the contents of the largest tank in the event of a rupture.

5.7.15.2.3 Exposures from Air Pathways

Sources of radionuclide emissions are Pb-210, natural uranium, Ra-226, and Th-230 released into the atmosphere from the land application areas. The land application areas could also be a source of Rn-222. Since the radium is precipitated before water is used in land application, this further reduces the potential impact to human health and the environment. The total effective dose equivalent (TEDE) to nearby residents in the region and at the facility boundaries was estimated using MILDOS-AREA. The parameters used to estimate releases are provided in Table 5.7-5.

Table 5.7-5 Parameters Used to Estimate Radionuclide Releases from the Project Site

Parameter	Value	Unit	Variable Name	Source
Rate of land application - Dewey	3.05E-03	$m\ d^{-1}$	AR_{Dewey}	Application
Rate of land application - Burdock	2.29E-03	$m\ d^{-1}$	$AR_{Burdock}$	Application
Area of land application - Dewey	1.82E+06	m^2	LA_{Dewey}	Application
Area of land application - Burdock-1	1.01E+05	m^2	$LA_{Burdock-1}$	Application
Area of land application - Burdock-2	1.82E+06	m^2	$LA_{Burdock-2}$	Application
Area of land application - Burdock-3	5.06E+05	m^2	$LA_{Burdock-3}$	Application
Time of land application in a year	136	d	t_d	Application
Years of land application	15	y	t_y	Application
Concentration of natural uranium in water	300	$pCi\ L^{-1}$	$[U\text{-}nat]_{water}$	Application (NRC effluent values)
Concentration of thorium-230 in water	100	$pCi\ L^{-1}$	$[Th\text{-}230]_{water}$	Application (NRC effluent values)
Concentration of radium-226 in water	60	$pCi\ L^{-1}$	$[Ra\text{-}226]_{water}$	Application (NRC effluent values)
Concentration of lead-210 in water	10	$pCi\ L^{-1}$	$[Pb\text{-}210]_{water}$	Application (NRC effluent values)
Density of soil - Dewey	1.28	$g\ cm^{-3}$	$_{Dewey}$	Application
Density of soil - Burdock	1.24	$g\ cm^{-3}$	$_{Burdock}$	Application
Depth of contamination	0.15	m	x	Assumption
Distribution coefficient of natural uranium in loam soil	15	$cm^3\ g^{-1}$	$K_{d,U\text{-}nat}$	"Data Collection Handbook to Support Modeling Impacts of Radioactive Material in Soil" by Yu et al.
Distribution coefficient of thorium-230 in loam soil	3300	$cm^3\ g^{-1}$	$K_{d,Th\text{-}230}$	"Data Collection Handbook to Support Modeling Impacts of Radioactive Material in Soil" by Yu et al.
Distribution coefficient of radium-226 in loam soil	36000	$cm^3\ g^{-1}$	$K_{d,Ra\text{-}226}$	"Data Collection Handbook to Support Modeling Impacts of Radioactive Material in Soil" by Yu et al.
Distribution coefficient of lead-210 in loam soil	16000	$cm^3\ g^{-1}$	$K_{d,Pb\text{-}210}$	"Data Collection Handbook to Support Modeling Impacts of Radioactive Material in Soil" by Yu et al.
Soil volume water content - Dewey	0.91	unitless	w_{Dewey}	Application
Soil volume water content - Burdock	0.80	unitless	$w_{Burdock}$	Application
Rate of resuspension of radionuclides in surface soil	4E-06	h^{-1}	ARR	DOE Handbook "Airborne Release Fractions/Rates and Respirable Fractions for Nonreactor Nuclear Facilities" by the US Department of Energy

5.7.15.2.4 Source Term Estimates

The source terms used to estimate natural uranium, Pb-210, Ra-226, and Th-230 releases from the land application areas are calculated. The parameters used to estimate releases are provided in Table 5.7-5. In cases where site-specific information was not available, conservative values based on published information were used.

For purposes of modeling in MILDOS-AREA, the land application areas are consolidated into clusters. All the land application areas in Dewey are grouped into one cluster called “Dewey”. The land application areas in Burdock are sorted into three clusters. One cluster, “Burdock-1”, consists of one land application area northwest of the main plant. Another cluster, “Burdock-2”, consists of twelve land applications areas between the main plant and the Burdock-1 cluster. The last cluster, “Burdock-3”, consists of three land application areas southwest of the main plant. The locations of the sources representing the clusters are the centroids of the clusters.

The land application areas in Dewey have different soil properties than the land application areas in Burdock. As a result, the source terms for releases of the radionuclides are calculated separately for clusters in Dewey and Burdock. The radionuclide release rates are calculated using Equation 5.1 (from DOE Handbook “Airborne Release Fractions/Rates and Respirable Fractions for Nonreactor Nuclear Facilities” by the US Department of Energy, modified by adding a factor converting h^{-1} to y^{-1}):

$$ST_{cluster,\ nu} = MAR_{cluster,\ nu} * DR * ARR * RF * LPF * 8760 \qquad \text{(Equation 5.1)}$$

Where:

ST	=	Radionuclide (nu) release rate (Ci y^{-1})
MAR	=	Amount of radionuclide in soil (Ci)
DR	=	Fraction of radionuclides available for resuspension
ARR	=	Rate of resuspension of radionuclides in surface soil (h^{-1})
RF	=	Respirable fraction of resuspended radionuclides in surface soil
LPF	=	Fraction of resuspended radionuclides passing through filtering, if any
cluster	=	Dewey, Burdock-1, Burdock-2, or Burdock-3
8760	=	Factor to convert h^{-1} to y^{-1}

In order to be conservative, all of the radionuclides in the soil of the land application clusters are assumed to be available for resuspension and there is no filtering. Therefore, both DR and LPF are assumed to be 1.

In the DOE Handbook “Airborne Release Fractions/Rates and Respirable Fractions for Nonreactor Nuclear Facilities”, the listed ARR for a homogenous bed of powder exposed to ambient conditions is 4E-05 hr^{-1}. However, that value is for “freshly deposited material” and “it would be inappropriate to use” this value for “releases for long-term contamination (i.e. months to years).” The experiment from which the ARR of 4E-05 hr^{-1} was found measured a range of ARR’s of 4E-05 hr^{-1} to 4E-07 hr^{-1}. For calculations in this application, the mid-range value of 4E-06 hr^{-1} was used for the ARR.

Since land application is proposed to occur on several areas spread across the site, calculations of source terms are performed separately for Dewey and Burdock.

The radionuclide soil inventories resulting from land application are calculated using Equation 5.2:

$$\mathrm{MAR}_{\mathrm{cluster,nu}} = [\mathrm{nu}]_{\mathrm{soil,\,cluster}} * \mathrm{M}_{\mathrm{cluster}} * 10^{-12} \quad \text{(Equation 5.2)}$$

Where:

$[\mathrm{nu}]_{\mathrm{soil}}$ = Concentration of radionuclide (nu) in soil (pCi g^{-1})

M = Mass of soil with radionuclide (g)
10^{-12} = Factor to convert pCi to Ci

The mass of soil contaminated in the land application at Dewey is different from the mass of soil contaminated in the land application at Burdock due to different soil densities.

The mass of soil contaminated in each land application cluster is calculated using Equation 5.3:

$$\mathrm{M}_{\mathrm{cluster}} = \rho_{\mathrm{area}} * \mathrm{x} * \mathrm{LA}_{\mathrm{clsuter}} * 10^{6} \quad \text{(Equation 5.3)}$$

Where:

= Density of soil (g cm^{-3})

area = Dewey or Burdock

x = Depth of contamination (m)

LA = Area used in land application (m^2)

10^6 = Factor to convert cm^{-3} to m^{-3}

The concentrations of the various nuclides in the land application soils at Dewey and Burdock are calculated using Equation 5.4 (from "MILDOS-AREA: An Update with Incorporation of *In Situ* Leach Uranium Recovery Technology" by Faillace et al.):

$$[\mathrm{nu}]_{\mathrm{soil,\,cluster}} = \frac{[\mathrm{nu}]_{\mathrm{water}} * \mathrm{V}_{\mathrm{cluster}} * \mathrm{R}_{\mathrm{s,area,nu}} * 10^{-3}}{\mathrm{LA}_{\mathrm{cluster}} * \mathrm{x} * \rho_{\mathrm{area}}} \quad \text{(Equation 5.4)}$$

Where:

$[nu]_{water}$ = Concentration of radionuclide in treated water (pCi L^{-1})

V = Volume of treated water used in land application (m^3)

R_s = Fraction of radionuclide in treated water retained in soil

10^{-3} = Factor to convert L^{-1} to cm^{-3}

The volume of treated water used in land application is calculated using Equation 5.5:

$$V_{cluster} = AR_{area} * t_d * t_y * LA_{cluster} \quad \text{(Equation 5.5)}$$

Where:

AR = Rate of land application (m d^{-1})

t_d = Time of land application in a year (d y^{-1})

t_y = Time of land application (y)

The area of land application is calculated in Equation 5.6:

The fraction of radionuclide in treated water retained in soil is calculated using Equation 5.6 (from "MILDOS-AREA: An Update with Incorporation of *In Situ* Leach Uranium Recovery Technology" by Faillace et al.):

$$R_{s,\,area,\,nu} = 1 - \frac{1}{R_{d,area,nu}} \quad \text{(Equation 5.6)}$$

Where:

R_d = Retardation factor

The retardation factor is calculated using Equation 5.7 (from "MILDOS-AREA: An Update with Incorporation of *In Situ* Leach Uranium Recovery Technology" by Faillace et al.):

$$R_{d,\,area,\,nu} = 1 + \frac{\rho_{area} * K_{d,\,nu}}{w_{area}} \quad \text{(Equation 5.7)}$$

Where:

K_d = Distribution coefficient (cm^3 g^{-1})

w = Soil volume water content

Using the parameters in Table 5.7-5 and Equations 5.1-7, the release rates are calculated for natural uranium (U-Nat), thorium-230 (Th-230), radium-226 (Ra-226), and lead (Pb-210) and shown in Table 5.7-6.

Table 5.7-6 **Estimated Soil Concentrations (pCi g^{-1}) and Release Rates (Ci y^{-1}) from the Project Site**

Location	X (km)	Y (km)	U-Nat		Th-230		Ra-226		Pb-210	
			Soil Conc.	Rel. Rate	Soil Conc.	Rel. Rate	Soil Conc.	Rel. Rate	Soil Conc.	Rel. Rate
Land Application - Dewey	-5.67	4.09	9.28	0.114	3.24	0.0397	1.94	0.0238	0.324	0.00397
Land Application - Burdock-1	-1.48	2.31	7.22	0.00476	2.51	0.00165	1.51	0.000992	0.251	0.000165
Land Application - Burdock-2	-0.90	1.10	7.22	0.0857	2.51	0.0298	1.51	0.0179	0.251	0.00298
Land Application - Burdock-3	-1.57	-1.50	7.22	0.0238	2.51	0.00828	1.51	0.00497	0.251	0.000828

5.7.15.2.5 Source Term Estimates – Rn-222

Sources of radon emanation are the land application areas, the well fields, the CPP, and resin transfers in the SF. The well fields consist of production well fields, restoration well fields, and new well fields. In order to be conservative, the well field in Dewey closest upwind to a receptor (Mining Unit 5) was modeled in MILDOS-AREA. Likewise, the mining unit in Burdock closest upwind to a receptor (Mining Unit 2) was modeled in MILDOS-AREA.

5.7.15.2.6 Land Application Releases

In addition to natural uranium, Ra-226, Pb-210, and Th-230; the land application areas are also sources of Rn-222. The radon source term is calculated using Equation 5.8 and the parameters listed in Table 5.7-6:

$$ST_{cluster} = J_{cluster} * A_{cluster} * 3.15 * 10^{-5} \qquad \text{(Equation 5.8)}$$

Where:

J = Radon flux (pCi m^2 s^{-1})

3.15 * 10^{-5} = Factor to convert pCi s^{-1} to Ci y^{-1}

The radon flux is calculated using Equation 5.9 (from RG 3.64):

$$J_{cluster} = [\text{Ra - 226}]_{soil,cluster} * \rho_{area} * E_{area} * \sqrt{\lambda * D_{area}} * 10^4 * \tanh\left(x * \sqrt{\frac{\lambda}{D_{area}}}\right) \qquad \text{(Equation 5.9)}$$

Where:

E = Radon emanation coefficient

= Radon-222 decay constant (2.1E-06 s^{-1})

D = Radon diffusion coefficient (cm^2 s^{-1})

10^4 = Factor to convert cm^{-2} to m^{-2}

The radon diffusion coefficient is calculated using Equation 5.10 (from RG 3.64):

$$D_{area} = 0.07 * e^{\left[-4*\left(w_{area} - n_{area}{}^{2} * w_{area} + w_{area}{}^{5}\right)\right]} \qquad \text{(Equation 5.10)}$$

Where:

n = Porosity

Using the parameters listed in Table 5.7-5 and Equations 5.8-10, the release rates of Rn-222 from land application are calculated. The releases are 7.43 Ci y^{-1} for Dewey, 0.38 Ci y^{-1} for Burdock-1, 6.88 Ci y^{-1} for Burdock-2, and 1.91 Ci y^{-1} for Burdock-3.

5.7.15.2.7 Production Releases

Plans are to have up to two mine areas which potentially could be mined concurrently. The potential Rn-222 releases from the production well fields were estimated using methods described in RG 3.59 as follows:

The yearly radon released to the production fluid is calculated using Equation 5.11:

$$Y = 1.44 * G * M_{production} * D * (1 - e^{-\lambda * t}) \qquad \text{(Equation 5.11)}$$

Where:

Y= Yearly radon released to production fluid (Ci y^{-1})

G = Radon released at equilibrium (Ci m^{-3})

M = Lixiviant flow rate (L min^{-1})

D = Production days per year (d)

λ = Radon-222 decay constant (d^{-1})

t = Lixiviant residence time

1.44 = Factor to convert L min^{-1} to m^3 y^{-1}

Radon released (equilibrium condition) to production fluid from leaching is calculated using Equation 5.12:

$$G = R * \rho_{form} * E * \frac{(1 - n_{form})}{n_{form}} * 10^{-6} \quad \text{(Equation 5.12)}$$

Where:

G = Radon released (Ci m^{-3})

R = Radium content of ore (pCi g^{-1})

E= Radon emanation coefficient

ρ_{form} = Formation density (g cm^{-3})

n_{form} = Formation porosity

Using Equations 5.11-12 and the parameters listed in Table 5.7-5, the yearly radon released to production fluid is 2117 Ci y^{-1}. RG 3.59 assumes all the Rn-222 that is released to the production fluid is ultimately released to the atmosphere which in the case of ion exchange columns operating at atmospheric pressure in an open system is an appropriate conservative assumption. In cases where pressurized downflow ion exchange columns are used, and well fields are operated under pressure, the majority of radon released to the production fluid stays in solution and is not released. The radon which is released is from occasional well field venting for sampling events, small unavoidable leaks in well field and ion exchange equipment, and maintenance of well field and ion change equipment. For this reason, estimated annual releases of 10 percent of the Rn-222 in the production fluid would occur in the well fields and an additional 10 percent in the ion exchange circuit was assumed. Given these assumptions, the annual Rn-222 released from production in the well field and at the main plant facility is 212 and 191 Ci y^{-1}, respectively. Since the satellite facility is planned to operate at the same parameters as the main plant facility, the annual Rn-222 released from production in the well field and at the satellite facility is also 212 and 191 Ci y^{-1}, respectively. This 10 percent release rate also includes Rn-222 released from the 1-5 percent bleed from the production well field.

5.7.15.2.8 Restoration Releases

Radon-222 releases resulting from well field restoration activities were estimated in the same manner as the production activities above (i.e. using Equations 5.11-12) but modified for the lower restoration flow rate listed in Table 5.7-5. The assumption of a 10 percent release in the well field and the main plant facility results in releases of 26.5 and 23.8 Ci y^{-1}, respectively. Since the satellite facility is planned to operate at the same parameters as the main plant facility, the annual Rn-222 released from production in the well field and at the satellite facility is also 26.5 and 23.8 Ci y^{-1}, respectively.

5.7.15.2.9 New Well Field Releases

Radon-222 releases resulting from new well field development activities were estimated using methods described in NUREG-1569*, Standard Review Plan for In Situ Leach Uranium Extraction License Applications* (NUREG-1569) by the US Nuclear Regulatory Commission as follows:

The yearly radon released new well field development is calculated using Equation 5.13:

$$Rn_{nw} = E * L * [Ra]_{ore} * T * m * N * 10^{-12} \qquad \text{(Equation 5.13)}$$

Where:

Rn_{nw} = Radon-222 release rate from new well field (Ci y^{-1})

$[Ra]_{ore}$ = Concentration of radium-226 in ore (pCi g^{-1})

L = Decay constant of radon-222 (0.181 d^{-1})

T = Storage time in mud pit (d)

m = Average mass of ore material in the pit (g)

N = Number of mud pits generated per year (y^{-1})

10^{-12} = Factor to convert pCi to Ci

Using Equation 5.13 and the parameters listed in Table 5.7-5, the yearly radon released from new well field development is 3.6E-05 Ci yr^{-1}.

5.7.15.2.10 Resin Transfer Releases

Radon-222 releases resulting from resin transfers at the SF are estimated using methods described in NUREG-1569 as follows:

The yearly radon released new well field development is calculated using Equation 5.14:

$$Rn_x = 3.65 * 10^{-10} * F_i * C_{Rn} \qquad \text{(Equation 5.14)}$$

Where:

Rn_x = Radon release rate from resin transfers (Ci y^{-1})

F_i = Water discharge rate from resin unloading (L d^{-1})

C_{Rn} = Steady state radon-222 concentration in process water (pCi L^{-1})

$3.65 * 10^{-10}$ = Factor to convert pCi d^{-1} to Ci yr^{-1}

The steady state radon-222 concentration in process water can be estimated using Equation 5.15:

$$C_{Rn} = \frac{Y * 1.9 * 10^6}{M} \qquad \text{(Equation 5.15)}$$

Where:

C_{Rn} = Steady state radon-222 concentration in process water (pCi L^{-1})

Y = Yearly radon released to production fluid (Ci y^{-1})

M = Lixiviant flow rate (L min^{-1})

$1.9 * 10^6$ = Factor to convert Ci y^{-1} to pCi min^{-1}

The water discharge rate from resin unloading (F_i) can be estimated using Equation 5.16:

$$F_i = N_{resin} * V_i * P_i \quad \text{(Equation 5.16)}$$

Where:

F_i = Water discharge rate from resin unloading (L d^{-1})

N_i = Number of resin transfers per day (d^{-1})

V_i = Volume of resin in transfer (L)

n_{resin} = Porosity of resin

Using Equations 5.13-16 and the parameters listed in Table 5.7-5, the yearly radon released from resin transfers at the SF is 0.523 Ci y^{-1}. This assumes the ore grade mined at the SF would yield the same radon concentration in production fluid as at the CPP.

5.7.15.2.11 Radon-222 Release Summary

A summary of estimated radon-222 releases from the site is presented in Table 5.7-7. The source coordinates in Table 5.7-7 are relative to the CPP. In the unlikely occurrence of an unmitigated event, doses to the workers could have a MODERATE impact depending on the type of accident, but doses to the general public would have only a SMALL impact (NUREG-1910, 2008).

Table 5.7-7 Estimated Releases (Ci y^{-1}) of Radon-222 from the Project Site

Location	X (km)	Y (km)	Production	Restoration	Drilling	Resin Transfer	Land Application	Total

5.7.15.2.13 Miscellaneous Parameters

The meteorological data used in the MILDOS-AREA model is from the joint frequency distribution data presented in Section 5.5 of this application.

The population distribution used in the MILDOS-AREA model to estimate population doses is from the demographic information presented in Section 5.7.14 of this application.

5.7.15.2.14 Total Effective Dose Equivalent to Individual Receptors

In order to show compliance with the annual dose limit found in 10 CFR part 20.1301, Powertech (USA) has demonstrated by calculation that the total TEDE to the individual most likely to receive the highest dose from the project uranium in situ leach operation is less than 100 mrem y^{-1}. Additionally, the annual effective dose equivalent (EDE) limit found in 40 CFR part 190 of 25 mrem y^{-1} was not exceeded at any receptors. The results of the MILDOS-AREA simulation for each receptor in Table 5.7-5 are presented in Table 5.7-9. The output from the MILDOS-AREA simulation for the land application option is in Appendix 5.7-D. The output for the MILDOS-AREA simulation for the deep well disposal option is in Appendix 5.7-E.

An evaluation of the TEDE calculations follows:

- The maximum 40 CFR part 190 EDE of 10.8 mrem y^{-1}, located at the property boundary north-northwest of the SF, is 43.2 percent of the public dose limit of 25 mrem y^{-1}. The 40 CFR 109 TEDE public dose limit is not exceeded at any boundary receptor. If the land application sources were excluded from the MILDOS-AREA model, no doses would exceed the 40 CFR part 190 dose limit since this limit specifically excludes sources of radon-222.
- The maximum total TEDE of 12.5 mrem per year, located at the property boundary north-northwest of the SF, is 12.5 percent of the 10 CFR 20 public dose limit of 100 mrem y^{-1}. The 10 CFR 20 public dose limit is not exceeded at any property boundary. If the land application sources were excluded form the MILDOS_AREA model, the TEDE at this location would be 2.5 mrem y^{-1}.
- The maximum 40 CFR part 190 EDE at a resident is 2.32 mrem y^{-1}, located at Spencer Ranch. This is 9.28 percent of the public dose limit of 25 mrem y^{-1}. None of the resident receptors have 40 CFR part 190 EDEs exceeding the 25 mrem y^{-1} public dose limit. None of these estimated EDEs exceed the 10 CFR 20 constraint rule for airborne effluents of 10 mrem y^{-1}. If the land application sources were excluded from the MILDOS-AREA model, no doses would exceed the 40 CFR part 190 dose limit for reasons discussed above.
- The maximum TEDE at a resident is 4.48 mrem y^{-1}, located at Spencer Ranch. It is 4.48 percent of the 10 CFR 20 public dose limit of 100 mrem y^{-1}. None of the residents have TEDEs exceeding the 100 mrem y^{-1}public dose limit. If the land application sources were excluded from the MILDOS-AREA model, the TEDE at this location would be 1.72 mrem y^{-1}.

Table 5.7-9 Estimated Total Effective Dose Equivalents (TEDE) to Receptors near the Project Site

Receptor	Distance from Main Plant (km)	40 CFR part 190 TEDE (mrem y^{-1})	Total TEDE (mrem y^{-1})

5.7.15.2.15 Population Dose

The annual population dose commitment to the population in the region within 80 km of the project site is also predicted by the MILDOS-AREA code. The results are contained in Table 5.7-10 where TEDE is expressed in terms of person-rems. For comparison, the dose to the population within 80 km of the facility due to background radiation has been included in the table. Background radiation doses are based on a North American population of 346 million and an average TEDE of 360 mrem.

The atmospheric release of radon also results in a dose to the population on the North American continent. This continental dose is calculated by comparison with a previous calculation based on a 1 kilocurie release near Casper, Wyoming, during the year 1978. The results of these calculations are included in Table 5.7-10. These calculations are also combined with the dose to the region within 80 km (50 miles) of the facility to arrive at the total radiological effects of one year of operation at the project site. The maximum radiological effect of the project operation would be to increase the TEDE of continental population by 7.5E-6 percent.

Table 5.7-10 Total Effective Dose Equivalent to the Population from One Year's Operation at the Project Site

Criteria	TEDE (person rem/yr)
Dose received by population within 80 km of the facility	0.879
Dose received by population beyond 80 km of the facility	8.13
Total continental dose	9.01
Background North American dose	1.2E8
Fractional increase to background dose	7.5E-8

5.7.15.2.16 Exposure to Flora and Fauna

MILDOS-AREA estimates surface deposition rates of Ra-226 and its decay products as a function of distance from the source and calculates surface concentrations. Table 5.7-11 presents the highest surface concentrations of Ra-226 and its decay products predicted by MILDOS-AREA over a 100-year period. Soil concentrations were calculated based on a conservative assumption of 1.5 g cm^{-3} bulk soil density.

Table 5.7-11 Highest Surface Concentrations of Radium-226 and its Decay Products

Radionuclide	Distance from site (km)	Direction	Surface concentration (pCi m^{-2})	Soil concentration in upper 15cm (pCi g^{-1})
Radium-226	1.5	WNW	9.94E+03	0.0442
Polonium-218	1.5	WNW	9.94E+03	0.0442
Lead-214	1.5	WNW	9.94E+03	0.0442
Bismuth-214	1.5	WNW	9.94E+03	0.0442
Lead-210	15.0	S	254	1.13E-3

The largest increase in soil concentration is 0.0442 pCi g^{-1} of radium-226, polonium-218, lead-214, and bismuth-214. Recent site specific surface soil (0-15 cm) data show that the background concentration of radium-226 ranges from 0.76 (25 percentile) to 2.2 (75 percentile) pCi g^{-1} with a geometric mean of 1.3 pCi g^{-1} and geometric standard deviation of 1.3 pCi g^{-1}. The increase in soil radioactivity is less than the geometric mean soil radioactivity prior to operations and if added to the geometric mean (1.3 pCi g^{-1}) is still within normal background variability observed at the site. Assuming the most important pathways to flora and fauna exposure start with radionuclide concentrations in soil, the impacts from normal site operations would be minimal and probably not distinguishable from background.

5.7.15.2.17 Determination of Radium Benchmark Dose

RESRAD was used to model the ISL site and calculate the maximum annual dose rate from the current radium cleanup standard.

The following supporting documentation for determination of the radium benchmark dose and the natural uranium soil standard is attached in the Appendix 5.7-F (Radium Benchmark Dose Assessment, ERG, Inc., Oct., 2008):

- The RESRAD Data Input Basis (Attachment 1 of Appendix 5.7-F) provides a summary of the modeling performed with RESRAD and the values that were used for the input parameters. A sensitivity analysis was performed for parameters which are important to the major component dose pathways and for which no site specific data was available.
- Selected graphs produced with RESRAD that present the results of the sensitivity analysis performed on the input parameters are attached (Attachment 2 of Appendix 5.7-F).
- A full printout of the final RESRAD modeling results for the resident farmer scenario with the chosen input values is attached (Attachment 3.0 and 3.1 of Appendix 5.7-F). The printout provides the modeled maximum annual dose for calculated times for the 1,000-year time span and provides a breakdown of the fraction of dose due to each pathway.
- Graphs produced with RESRAD that present the modeling results for the maximum dose during the 1,000 year time span for radium-226 and natural uranium. A series of graphs depicting the summed dose for all pathways and the component pathways that contributes to the total dose are attached (Attachment 4.0 and 4.1 of Appendix 5.7-F).

The maximum dose from Ra-226 contaminated soil at the 5 pCi/g above background cleanup standard, as determined by RESRAD, for the residential farmer scenario was 38.1 mrem/year. This dose was based upon the 5 pCi/g surface (0-6-inch) Ra-226 standard and was noted at time, t = 0 years. The two major dose pathways were external exposure and plant ingestion (water independent). For these two pathways, a sensitivity analysis was performed for important parameters for which no site specific information was available. The 38.1 mrem/year dose from radium is the level at which the natural uranium radiological end point soil standard will be based as described in the following section.

5.7.15.2.18 Determination of Natural Uranium Soil Standard

RESRAD was used to determine the concentration of U-nat in soil distinguishable from background that would result in a maximum dose of 38.1 mrem/year. The method involved modeling the dose from a set concentration of U-nat in soil. This dose was then compared to the radium benchmark dose and scaled to arrive at the maximum allowable U-nat concentration in soil.

For ease of calculations, a preset concentration of 100 pCi/g U-nat was used for modeling the dose. The fractions used were 49.2 percent (or pCi/g) U-234, 48.6 percent (or pCi/g) U-238 and 2.2 percent (or pCi/g) U-235. The distribution coefficients that were selected for each radionuclide were RESRAD default values. All other input parameters were the same as those used in the Ra-226 benchmark modeling.

Using a U-nat concentration in soil of 100 pCi/g, RESRAD determined a maximum dose of 7.1 mrem/year, at time, t = 0 years. The printout of the RESRAD data summary is provided in Attachment 3.1 of Appendix 5.7-G and the dose figures generated with RESRAD are provided in Attachment 4.1 of Appendix 5.7-F.

To determine the uranium soil standard, the following formula was used:

$$\text{Uranium Limit} = \left(\frac{100 \text{ pCi/g U - nat}}{7.1 \text{ mrem/yr U - nat dose}} \right) \text{x } 38.1 \text{ mrem/yr radium benchmark dose}$$

$$\text{Uranium Limit} = 537 \text{ pCi/g U - nat}$$

The U-nat limit is applied to soil cleanup with the Ra-226 limit using the unity rule. To determine whether an area exceeds the cleanup standards, the standards are applied according to the following formula:

$$\left(\frac{\text{Soil Uranium Concentration}}{\text{Soil Uranium Limit}}\right)+\left(\frac{\text{Soil Radium Concentration}}{\text{Soil Radium Limit}}\right) < 1$$

This approach will be used at the ISL site to determine the radiological impact on the environment from releases of source and byproduct materials.

5.7.15.3 Uranium Chemical Toxicity Assessment

The chemical toxicity effects from uranium exposure are evaluated by assuming the same exposure scenario as that used for the radiation dose assessment. In the benchmark dose assessment for the resident farmer scenario, it was assumed that the diet consisted of 25 percent of the meat, fruits, and vegetables grown at the site. No intake of contaminated food through the aquatic or milk pathways was considered probable. Also, the model showed that the contamination would not affect the groundwater quality. Therefore, the same model will be used in assessing the chemical toxicity. The intake from eating meat was shown to be negligible compared to the plant pathway and therefore is not shown here. This is confirmed by the results of the RESRAD calculations shown in Attachment 3.1 of Appendix 4.14-B and the figures generated with RESRAD shown in Attachment 4.1 of Appendix 5.7-F.

The method and parameters for estimating the human intake of uranium from ingestion are taken from NUREG/CR-5512 Vol. 1 (NRC, 1992). The uptake of uranium in food is a product of the uranium concentration in soil and the soil-to-plant conversion factor. The annual intake in humans is then calculated by multiplying the annual consumption by the uranium concentration in the food. Since the soil-plant conversion factor is based on a dry weight, the annual consumption must be adjusted to a dry-weight basis by multiplying by the dry-weight to wet-weight ratio. Parameters for these calculations are given in Section 6.5.9 of the NUREG/CR-5512 Vol. 1 (NRC, 1992). Table 5.7-12 provides the parameters used in these calculation and results for leafy vegetables, other vegetables, and fruit. Annual intakes of 14 kg/year and 97 kg/year were assumed for leafy vegetables and other vegetables and fruit, respectively. Consistent with Attachment 3.1 of Appendix 4.14-B dose calculations, it was assumed that 25 percent of the food was grown on the site. It was also assumed that the uranium concentration in the garden or orchard was 537 pCi/g. This corresponds to the uranium Benchmark Concentration for surface soils. Using a conversion factor for U-nat of 1 mg = 677 pCi, then 537 pCi/g is equivalent to 793 mg/kg. The human intake shown in the second column of Table 5.7-12 is equal to the product of the parameters given in the subsequent columns. Table 5.7-12 shows that the total annual uranium intake from all food sources from the site is 52.4 mg/year.

The two-compartment model of uranium toxicity in the kidney from oral ingestion was used (ICRP, 1995) to predict the burden of uranium in the kidney following chronic uranium ingestion. This model allows for the distribution of the two forms of uranium in the blood, and consists of a kidney with two compartments, as well as several other compartments for uranium distribution, storage and elimination including the skeleton, liver, red blood cells (macrophages) and other soft tissues.

Table 5.7-12 Annual Intake of Uranium from Ingestion

Food Source	Human Intake (mg/yr)	Soil Concentration (mg/kg)	Soil to Plant Ratio (mg/kg plant to mg/kg soil)	Annual Consumption (kg)	Dry Weight Wet Weight Ratio
Leafy Vegetables	9.4	793	1.7E-2	3.5	0.2
Other Vegetables	36.1	793	1.4E-2	13	0.25
Fruit	6.9	793	4.0E-3	12	0.18
Total	52.4				

The total burden to the kidney is the sum of the two compartments. The mathematical representation for the kidney burden of uranium at steady state can be derived as follows (ICRP, 1995):

$$Q_P = \frac{IR \times f_1}{\lambda_P \left(1 - f_{ps} - f_{pr} - f_{pl} - f_{pk} - f_{pk1}\right)}$$

Where:

Q_P = uranium burden in the plasma, μg

IR = dietary consumption rate, mg U/d

f_1 = fractional transfer of uranium from GI tract to blood, unitless

f_{ps} = fractional transfer of uranium from plasma to skeleton, unitless

f_{pr} = fractional transfer of uranium from plasma to red blood cells, unitless

f_{pl} = fractional transfer of uranium from plasma to liver, unitless

f_{pt} = fractional transfer of uranium from plasma to soft tissue, unitless

f_{pk1} = fractional transfer of uranium from plasma to kidney, compartment 1, unitless

λ_p = biological retention constant in the plasma, d^{-1}

The burden in kidney compartment 1 is:

$$Q_{k1} = \lambda_P \times Q_P \times \frac{f_{pk1}}{\lambda_{k1}}$$

Where:

Q_{k1} = uranium burden in kidney compartment 1, mg

λ_{k1} = biological retention constant of uranium in kidney compartment 1, d^{-1}

Similarly, for compartment 2 in the kidney, the burden is:

$$Q_{k2} = \lambda_P \times Q_P \times \frac{f_{pk2}}{\lambda_{k2}}$$

Where:

Q_{k2} = uranium burden in kidney compartment 2, µg

λ_{k2} = biological retention constant of uranium in kidney compartment 2, d^{-1}

f_{pk2} = fractional transfer of uranium from plasma to kidney compartment 2, unitless

The total burden to the kidney is then the sum of the two compartments is:

$$Q_{k1} + Q_{k2} = \frac{IR \times f_1}{\left(1 - f_{ps} - f_{pr} - f_{pl} - f_{pt} - f_{pk1}\right)} \times \left(\frac{f_{pk1}}{\lambda_{k1}} + \frac{f_{pk2}}{\lambda_{k2}}\right)$$

The parameter input values for the two-compartment kidney model include the daily intake of uranium estimated for residents at this site, and the ICRP69 values recommended by the ICRP as listed below (ICRP, 1995). The daily uranium intake rate was estimated to be 0.14 mg/day (52.4 mg/year) from ingestion while residing at this site.

IR = 0.14 mg/day

f_1 = 0.02

f_{ps} = 0.105

f_{pr} = 0.007

f_{pl} = 0.0105

f_{pt} = 0.347

f_{pk1} = 0.00035

f_{pk2} = 0.084

$_{k1}$ = ln(2)/(5 years*365 days/year)

$_{k2}$ = ln(2)/7 days

where ln(2) = 0.693…

Given a daily uranium intake of 0.14 mg/day at this site and the above equation, the calculated uranium in the kidneys is 0.0093 mg U, or a concentration of 0.032 µg U/g kidney. This is 3.2 percent of the 1.0 µg U/g value that has generally been understood to protect the kidney from the toxic effects of uranium.

Some researchers have suggested that mild effects may be observable at levels as low as 0.1 μg U/g of kidney tissue. Using 0.1 μg U/g as a criterion, then the intake is 32 percent of the level where mild effects may be observable.

The EPA evaluated the chemical toxicity data and found that mild proteinuria has been observed at drinking water levels between 20 and 100 μg/L. Assuming water intake of 2 L/day, this corresponds to an intake of 0.04 to 0.2 mg/day. Using animal data and a conservative factor of 100, the EPA arrived at a 30 μg/L limit for use as a National Primary Drinking Water Standard (Federal Register/Vol.65, No.236/ December 7, 2000). This is equivalent to an intake of 0.06 mg/day for the average individual. Naturally, since large diverse populations are potentially exposed to drinking water sources regulated using these standards, the EPA is very conservative in developing limits.

This analysis indicates that a soil limit of 537 pCi/g of U-nat would result in an intake of approximately 0.14 mg/day. Using the most conservative daily limit corresponding to the National Primary Drinking Water standard, a soil limit of 230 pCi/g corresponds to the EPA intake limit from drinking water with a uranium concentration of 0.06 mg/day. Therefore exposure to soils containing 230 pCi/g of natural uranium should not result in chemical toxicity effects. Since the roots of a fruit tree would penetrate to a considerable depth, limiting subsurface uranium concentrations to 230 pCi/g will be considered.

The ALARA principle requires an evaluation of, considering a cost benefit analysis and socio-economic impacts, the practicality of lowering established or derived soil cleanup levels. For gamma-emitting radionuclides, the cost and impacts becomes excessively high as soil concentrations, thus the gamma emission rates, become indistinguishable from background.

Cleanup of uranium mill sites has demonstrated that conservatively derived gamma action levels coupled with appropriate field survey and sampling procedures result in radium-226 soil concentrations near background levels. The presents of radium-226 and natural uranium in a mixture will tend to drive the cleanup to lower radium-226 concentrations. The ALARA principle is met by choosing conservatively derived gamma actions levels, thus no ALARA goals for radium-226 need to be established.

Powertech (USA) Uranium USA proposes an ALARA goal of limiting the natural uranium concentration in the top 15 cm soil layer to 150 pCi/g averaged over the impacted areas. Subsurface soil (greater than 15 cm) natural uranium concentrations should be limited to 230 pCi/g averaged over the impacted area based on chemical toxicity.

5.7.15.4 Potential Radiological Accidents

The following section discusses potential impacts from radiological accidents. Section 5.8.2 discusses the mitigation measures that will be taken to reduce or eliminate these potential impacts.

5.7.15.4.1 Potential Tank Failure

The tanks at the PAA will contain injection and production solutions, ion exchange resin, pregnant eluant, yellowcake, and liquid waste. All tanks will be constructed with the proper material (e.g., fiberglass, steel or aluminum) to adequately contain to the stored material. Instantaneous tank failure is unlikely, but a small leak in the tank would be more probable. In the event of a leak, the tank would be repaired or replaced as necessary.

An NRC sponsored study contained in NUREG/CR-6733 evaluated the potential impacts from the failure of a yellowcake thickener, which resulted in the release of 20% of the thickener volume escaped outside the processing building, based on an event at the Irigaray ISL facility in 1994. NUREG/CR-6733 calculated that the public dose would be below the limits in 10 CFR Part 20 and the dose to an unprotected worker would exceed the 5 rem exposure limits from 10 CFR Part 20. This calculation contains several conservative assumptions, such as the yellowcake would become dry and transportable because no effort would be made to clean up the spill, and that the dose calculation negates the use of protective equipment, and finally, the dose was based on lung clearance class Y uranium, which produces the highest dose estimates.

This study also calculated the potential dose from a catastrophic release of the entire contents from an ion exchange column and the subsequent release of radon gas. The calculated dose for a 30-minute period to a worker in the area would be 1.3 rem. NUREG/CR-6733 recommends that the use of ventilation or atmosphere-supplying respirators designed to protect against gases should be sufficient to mitigate such doses, that unprotected personnel should evacuate the spill areas near areas that have pregnant lixiviant feeds, such as the ion-exchange columns and report any spills immediately, and that ISL facilities maintain proper equipment, training, and procedures to respond to large lixiviant spills or IX column failure.

5.7.15.4.2 Potential Plant Pipe Failure

In the event of the rupture of a plant pipe, operating staff would easily detect rupture and would quickly contain and manage the spilled solution following the same procedures outlined for a tank failure.

5.7.15.4.3 Potential Well Field Spill

The failure of a process pipeline within the well field could result in the discharge of pregnant or barren lixiviant to the surface. In order to minimize the amount of process fluid that is lost should a failure occur, high and low pressure alarms and shutoffs as well as flowmeters will be installed on pipelines between the well field and the central processing plant. Should a failure occur and the amount and/or concentration of the process fluid lost constitute an environmental concern, then the affected area would have the contaminated soil surveyed and removed for disposal. Pipeline failure is minimized by burying the pipeline two to five feet below ground surface and inspecting and testing the piping prior to burial. Pressure test results for the piping will be documented. Corrosion free high density polyethylene (HDPE) or similar piping will be used to further reduce the chance of pipeline failure.

Small leaks at pipe joints and fittings in the header houses or at wellheads may occur occasionally. These leaks may drip process solutions onto the underlying soil until they are identified and repaired. Powertech (USA) will implement a program of continuous well field monitoring by roving well field operators including periodic inspections of each well, in order to identify and remedy small leaks. Small leaks rarely result in contamination of the underlying soil. Following repair, Powertech (USA) will survey the affected soil for contamination, and, if contamination is detected, the soil will be appropriately removed.

5.7.15.5 Waste Management

5.7.15.5.1 Gaseous and Airborne Particulates

The main radioactive airborne effluent of concern at an ISL facility is radon-222 gas. Radon-222 is found in the pregnant lixiviant which is transported into the facility from the well field for uranium separation. Ion exchange (IX) units will be used to separate the uranium from the groundwater by passing the solution through IX units operated in a pressurized downflow mode. Small amounts of radon-222 may potentially be released during solution spills, filter changes, IX resin transfer, reverse osmosis (RO) system operation during groundwater restoration, and various maintenance activities. These potential minimal radon gas releases generally occur on an infrequent basis. An exhaust system installed to ventilate radon-222 gas to the atmosphere from the CPP will reduce employee exposure. The air in the CPP and other facilities will be sampled for radon daughters to assure that radon and radon daughters are maintained at concentration levels as low as reasonably achievable (ALARA).

5.7.15.5.2 Liquid Waste

Sources of liquid waste are collected as a result of in situ leach production. The following sections represent potential liquid waste sources at the project.

5.7.15.5.3 Liquid Waste

Sources of liquid waste are collected as a result of in situ leach production. The following sections represent potential liquid waste sources at the project.

5.7.15.5.3.1 Liquid Process Waste

The primary source of liquid waste is the operation of the ion exchange process which generates production bleed. This bleed will be treated with ion exchange to remove uranium, arsenic and vanadium, with ferric hydroxide coagulants to remove arsenic if necessary and finally with barium chloride to remove radium before being either injected in a deep disposal well or used to irrigate alfalfa within the PAA using center-pivot sprinklers. Other sources of liquid waste from the central plant include plant wash down water and the waste streams from the elution and precipitation circuits; however, these liquid waste streams make up a much smaller portion of the total liquid waste stream at the project facility.

5.7.15.5.3.2 Water Collected from Well Field Releases

Injection lixiviant or leach fluids recovered from areas where a liquid release has occurred from a pipeline or well will be placed into the wastewater system for treatment and disposal.

5.7.15.5.3.3 Disturbed Area Runoff

Runoff from disturbed areas will be prevented from entering local waterways. The permitting process through DENR and Powertech (USA)'s Storm Water Management Plan (SWMP) provides confidence that potential environmental impacts will be limited. Facility drainage will be designed to contain disturbed area runoff. The design of the project facilities, combined with engineering and procedural controls contained in a Best Management Practices (BMP) Plan, will ensure that the disturbed area runoff is not a potential source of pollution.

5.7.15.5.3.4 Liquid Waste Disposal

5.7.15.5.3.4.1 Deep Well Disposal

The use of deep well injection alone or in combination with land application is being considered by Powertech (USA) to dispose of liquid waste. Exhibit 1.1-2 provides the facilities map depicting the deep well disposal option. The permitting of the wells will meet the criteria and standards promulgated by the Environmental Protection Agency under the regulatory provisions of 40 CFR Part 146, Underground Injection Control Program.

The physical and chemical properties of the wastes will be similar to the estimated quality of wastes provided in Table 5.7-13 for land application. The process waters for deep well injection will meet the regulatory provisions in 10 CFR 20.2002 and be within the dose limits in 10 CFR 20.1301.

5.7.15.5.3.4.2 Land Application

In the land application option of wastewater disposal, bleed water from the process circuit will be extracted and treated using ion-exchange columns to remove uranium and other metals. This water will be discharged to lined settling ponds, where radium will be precipitated with barium sulfate. Water from these ponds will then be pumped to center pivot sprinklers and used to irrigate alfalfa during the growing season (May 11 to September 24). Water from the ponds will be sampled before it is pumped to the sprinklers to ensure that it meets the applicable discharge standards for all constituents (Exhibit 1.1-1).

The design of the land application system was developed based on modeling using the SPAW model, which is described in detail in the Dewey-Burdock Pond Design Report located in Appendix 4.3-A.

The following Table 5.7-13 provides the estimated water quality to be applied to crops at both the Dewey and Burdock land application sites. It is anticipated that trace metal concentrations will be at or below EPA Primary Drinking Water Standards. In addition, the effluent concentration limits for the release of radionuclides to the environment as contained in 10 CFR Part 20, Appendix B will be met.

5.7.15.5.3.4.3 SPAW Model Description

The SPAW (Soil-Plant-Atmosphere-Water) Model was developed by the U.S. Department of Agriculture (Saxton and Willey, 2006) to simulate the daily hydrologic water budgets of agricultural landscapes by two connected routines, one for farm fields and one for impoundments such as irrigation ponds. The field hydrology simulation is represented by: 1) daily climatic descriptions of precipitation, temperature, and evaporation; 2) a soil profile of interacting layers each with unique water holding characteristics; and 3) annual crop growth with management options for rotations, irrigation, and fertilization. The model output for the field hydrology routine includes a daily vertical, one-dimensional water budget depth for all major hydrologic processes such as runoff, infiltration, evapotranspiration, soil water profiles, and percolation. Water volumes for each component of the water balance are estimated by multiplying the water budget depth times the associated field area.

Table 5.7-13 Estimated Land Application Water Quality

Analyte	Units	Dewey Land Application Estimate	Burdock Land Application Estimate
pH	s.u.	6.5-7.5	6.5-7.5
Eh	mV	350	350
cond.	mS/cm	3	4
Major Ions			
Bicarbonate	mg/L	<50	<50
Calcium	mg/L	270	330
Carbonate	mg/L	<1	<1
Chloride	mg/L	300-1300	300-1300
Sodium	mg/L	270	190
Sulfate	mg/L	1000	1800
Solids	mg/L	4000-5000	4000-5000
Minor Ions			
Arsenic	mg/L	0.01	0.01
Barium	mg/L	0.42	0.42
Cadmium	mg/L	0.34	0.34
Chromium	mg/L	0.38	0.38
Copper	mg/L	0.28	0.28
Iron	mg/L	1.1	0.2
Lead-210	mg/L	<10	<10
Magnesium	mg/L	120	220
Molybdenum	mg/L	<0.1	<0.1
Nickel	mg/L	340.34	340.34
Potassium	mg/L	20	10
Radium-226	pCi/L	<60	<60
Selenium	mg/L	<0.2	<0.2
Thorium 230	pCi/L	<100	<100
U-Nat	pCi/L	<300	<300
Uranium	mg/L	<0.2	<0.2
Vanadium	mg/L	<10	<10
Sodium Absorption Ratio		4.9	2.8
Cations	meq/L	36	43
Anions	meq/L	30	47
Zinc	mg/L	-	-
A/C balance	%	8	-4
TDS Calc.	mg/L	2043	2908

Notes:

1) Estimates of land application water quality were based on the results of laboratory scale leach tests conducted on ore samples from the Dewey (Fall River) and Burdock (Lakota) sites, as well as from historical end-of-mining water quality data from other ISL sites in Wyoming and Nebraska, with adjustments as necessary to account for planned post-mining water treatments.

2) For the anion computation, a chloride concentration of 300 mg/L was used.

3) For the calculated TDS computation, a chloride concentration of 800 mg/L was used.

Pond hydrology simulations provide water budgets by multiple input and depletion processes for impoundments whose water source is runoff from agricultural fields and/or water produced by wells or other sources. Model outputs for the pond hydrology routine include daily values of depth, volume, precipitation, evaporation, and change in storage for the period of simulation. The version of the SPAW model used was Version 6.02.75. The model has been extensively tested by the developers using research data and real-world applications.

5.7.15.5.3.4.4 Domestic Liquid Waste

Domestic liquid wastes from the restrooms and lunchrooms will be disposed of in an approved septic system that meets the requirements of the DENR. These systems are commonly used throughout the United States and the effect of the system on the environment is known to be minimal.

5.7.15.6 Solid Waste

5.7.15.6.1 Radioactive Solid Wastes

Solid radioactive waste generated at the site is expected to include impounded 11e.(2) byproduct material extracted directly from the ISL process (reverse osmosis units, spent resins, etc) as well as material contaminated with radionuclide byproducts (miscellaneous pipe, pumps, fittings and similar items contaminated with low levels of radioactive "scale" and precipitates). The radiological contaminant will be primarily residual natural uranium and radium 226 (NMA 2007, Brown 2007, 2008). As radium will follow the process calcium chemistry, process pH and related chemical parameters will play a role in determining where and how much residual byproduct material becomes deposited in process components. Mobilization of other radionuclides, in situ (Th 230, Pb 210), has been indicated to be minimal (Brown 1982).

5.7.15.6.2 Impounded Byproduct Material

Small volumes of solid radioactive wastes are typically generated at ISL facilities and need to be temporarily impounded at designated on-site locations pending further evaluation and/or shipment offsite. Temporary impoundment on-site typically involves designated ponds and/or tankage. Alternatively, the material may be drummed as produced.

These wastes result primarily from spent resins and process sludges, including pond sludges, reject streams/brine from reverse osmosis (RO) units, solid slurry precipitates from brine concentrators, spent sand and/or Cuno filters, filter back flush from similar process stream "polishing" activities and potentially small amounts of contaminated soil from leaks and/or spills, as well as contaminated equipment and supplies, such as personal protective equipment.

Byproduct material requiring offsite disposal in accordance with NRC requirements and/or license conditions will be transported off site to an NRC or Agreement State licensed 11e.(2) disposal facility. Powertech (USA) estimates that the proposed project will produce approximately 100 yd^3 of 11e.(2) byproduct material per year. These materials will be stored on-site, properly labeled and posted inside the restricted area until such time that a full shipment can be transferred to a licensed 11e.(2) waste disposal facility in accordance with the requirements of the NRC. Powertech (USA) will have a contract with an approved disposal facility for disposal of 11e.(2) material in place prior to beginning licensed production operations.

5.7.15.6.3 Contaminated Materials

This category of solid radioactive waste includes process and other ancillary equipment and materials that have become contaminated with low levels of byproduct materials as a result of use and/or contact with process streams. Equipment and materials generated by this proposed project that may become contaminated with byproduct materials include items such as rags, trash, worn or replaced parts from equipment, piping, fittings, pumps, filters, and protective clothing. In some cases, reusable items with economic value may be decontaminated prior to release from the restricted area. If decontamination of equipment is deemed desirable and practical, this will be performed using strict decontamination and according to radiation release criteria. Decontaminated materials must have activity levels lower than those specified in Table 2 of NRC Regulatory Guide 8.30 (NRC, 2002).

5.7.15.6.4 Hazardous Waste

The potential exists for any industrial facility to generate hazardous waste as defined by the Resource Conservation and Recovery Act (RCRA). On the basis of the processes and materials to be used on the project, it is likely that this project will be classified as a Conditionally Exempt Small Quantity Generator (CESQG), defined as a generator that generates less than 100 kilograms (kg) of hazardous waste in a calendar month and that complies with all applicable hazardous waste program requirements. Powertech (USA) expects that only used waste oil and universal hazardous wastes such as cleaning solvents and spent batteries will be generated at the project.

5.7.16 Potential Cumulative Impacts of Proposed Action

5.7.16.1 Potential Cumulative Impacts of Other Uranium Development Projects

The National Environmental Policy Act (NEPA) defines cumulative effects as "...impacts [that] can result from individually minor but collectively significant actions taking place over a period of time." The PAA is within the Nebraska – South Dakota – Wyoming Uranium Milling Region, which has a history of conventional uranium surface mining. According to the NUREG-1910, there were no identified coal mines within this uranium milling region that might affect the cumulative impacts of the project or other uranium developments.

Within the Edgemont Uranium District, uranium was first discovered in 1951 and subsequently mined for a number of years using conventional surface mining methods. There are no Source Material Licenses for ISL uranium projects within fifty miles of the PAA. The nearest operational ISL facility is the Crow Butte ISL facility, SUA-1534, in Darrow County, near Crawford, Nebraska (U.S. NRC, 2008). Considering the distance between the existing projects and the proposed project and the almost half acentury since the previous uranium development in the area, cumulative environmental impacts are considered to be small to negligible.

Powertech (USA) Inc. is currently investigating several prospective uranium ISL projects along with other companies within the Nebraska – South Dakota – Wyoming Uranium Milling Region. These projects are in various stages of development. At the time of this application Powertech (USA) is not aware of other licensing or permitting applications within the study area.

5.8 Mitigation Measures

Mitigation measures are those actions that can be taken to reduce potential adverse impacts and that will be incorporated into the Proposed Action and alternatives (40 CFR §§ Parts 1502.14(f) and 1508.20). The mitigation measures discussed in this Section are tangible and specific and cover the range of potential impacts of the Proposed Action. All relevant, reasonable mitigation measures that, to the extent practicable, can improve the Proposed Action are identified, even if they are outside NRC's jurisdiction. The anticipated effectiveness of the proposed mitigation measures in reducing potential adverse impacts, the technical feasibility, and the costs versus benefits of any recommended mitigation measures are discussed.

The following subsections provide greater detail on proposed mitigation measures that could be used to reduce potential adverse impacts presented in Section 4.0, including the following potential impacts of the Proposed Action: land use, transportation, geologic and soil, surface water, groundwater (hydrology), ecology, air quality, noise, historic and cultural resources, visual/scenic resources, socioeconomic resources, environmental justice, radioactive and non-radioactive risk and waste management.

As a general proposition and as will be shown below, active mitigation measures for ISL operations originate from two sources: (1) the nature of the ISL process and (2) NRC/Agreement State license conditions, which essentially are a series of protective or "mitigation" measures. Taken together, these measures will result in the licensed PAA exhibiting minimal, if any, evidence that site land and water (both surface and underground) resources will be impacted by licensed ISL operations.

5.8.1 Proposed Mitigation Measures for Potential Land Use Impacts from the Proposed Action

5.8.1.1 Surface Disturbance During Construction and Operation

As previously stated, the average estimated land disturbed per year for the life of the operation is a maximum of 108 acres. The following proposed procedures will be used to minimize the impacts of surface disturbance during construction and operation as previously discussed:

- Disturbance will be limited to only what is necessary for operations.
- Development of Quality Assurance Quality Control (QA/QC) plan to monitor the effectiveness of mitigation methods.
- Restrict normal vehicular traffic to designated roads and keep required traffic in other areas of the wellfield to a minimum.
- Use Class V deep disposal wells for disposal of liquid wastes to mitigate potential land use impacts.
- Conduct site ISL reclamation in interim steps to minimize potential land use environmental impacts. As noted above, sequential wellfield development results in minimizing land area impacted at any one time.
- Stockpile topsoil from the well sites, evaporation ponds, and facilities. Shape, seed the piles with a cover crop or mulch the stockpiles to control erosion.
- Evaporation or water treatment ponds, if used, will be reclaimed and re-vegetated and the land returned to its previous uses, or as otherwise agreed with the regulatory body and landowners.
- After groundwater restoration is completed, properly decommission each wellfield and remove or decontaminate in place all wellfield lines and pipelines. Upon decommissioning, all wells will be sealed and capped. As areas are restored, they will be backfilled, contoured, and smoothed to blend with the natural terrain in accordance with the surface reclamation plan.
- All process facilities will be decontaminated and removed unless they are to be used for other future activities; the Permit Area will regain its pre-operational features.

Upon completion of final site D&D, including surface reclamation, landowners will be contacted and given the option to retain the roads for their private use or have the roads reclaimed by Powertech (USA). If the roads are deemed beneficial to others (i.e., hunters, ranchers and residents) and the landowner agrees, the roads will not be reclaimed. Only roads related to the Proposed Action will be reclaimed.

5.8.2 Proposed Mitigation Measures for Potential Transportation Impacts from the Proposed Action

5.8.2.1 Mitigation of Access Road Construction Risk

The primary potential impacts associated with access road construction are relatively minor and consist mainly of air quality impacts from equipment exhaust and dust. The following proposed procedures will be used to minimize the impacts from transportation discussed in Section 5.7.3:

- Maintain access roads to minimize or eliminate truck accidents.
- Implement control of fugitive dust using water application and speed limits.
- Reduce maximum fugitive dust by coordinating construction and transportation activities.
- Maintain vehicles to meet applicable EPA emission standards.

5.8.2.1.1 Mitigation of Potential Impacts from Material Shipments of Supplies Sent and Received via the Process Facilities

The following proposed procedures will be used to minimize the impacts of the shipment activities discussed in Section 5.7.3.3:

- Compliance with all applicable NRC and DOT packaging and transport requirements.
- Use of SOPs for transportation and emergency response.
- Use dedicated tanker trucks for transporting loaded or barren/eluted (stripped) resins to and/or from CPP or SF facilities.
- Proper training will be required for relevant transport contractor personnel on how to respond to a transportation accident based on the specific material(s) shipped. Written procedures (SOPs) will accompany all drivers to ensure proper response to accidents and spill containment.
- Prior to each shipment of loaded or barren/eluted (stripped) resin or yellowcake the exterior and cab of the shipping truck will be surveyed for radiological contamination.
- Emergency response kits will be supplied to both the receiving and shipping facilities.
- Each resin or yellowcake transport vehicle will carry an emergency spill kit to help contain any spilled material.
- Shipping records (bill of landing) will be maintained to identify and quantity of material shipped.
- Both the transport vehicle and shipping facilities will be equipped with communication devices to enable direct communication with relevant Powertech (USA) personnel.
- For radiological accidents, notification will be provided to NRC in compliance with the requirements of 10 CFR €€ 20.2202 & 20.2203.
- Communication with local and State authorities on transportation and emergency response procedures.

When IX resins are fully loaded at the Dewey SF, such resins will be pumped (transferred) into dedicated tanker trucks and will be transported to the Burdock CPP where it will be pumped (transferred) into the CPP elution circuit. Trained Powertech (USA) personnel will comply with all Powertech (USA) SOPs for such activities to minimize potential impacts.

After proper cooling, yellowcake will be loaded into gasketed and sealed 55-gallon (208-L) steel drums at the Burdock CPP and will be transported to a conversion facility for further refining and conversion. A properly licensed and certified transportation contractor will transport resin and/or yellowcake from the PAA to a conversion facility in a manner consistent with all applicable NRC and DOT regulations and requirements.

In addition, all shipments of process chemicals, fuel and non-AEA radioactive materials will comply with applicable DOT hazardous materials shipping regulations and NRC requirements to further mitigate the potential impacts of a transportation accident.

5.8.3 Proposed Mitigation Measures for Geologic and Soil Impacts from the Proposed Action

Potential impacts to soils during all phases of the Proposed Action include soil compaction, loss of productivity, loss of soil, increased salinity, and soil contamination.

As noted in Section 5.7 of this ER, ISL production has not in the past and is not in the future expected to contribute to any potential, significant geological impacts. The following proposed measures will be used to minimize the potential impacts to soil resources discussed in Section 5.7.4.8:

- Salvage and stockpile soil from disturbed areas.
- Reestablish temporary or permanent native vegetation as soon as possible after disturbance utilizing the latest technologies in reseeding and sprigging, such as hydroseeding.
- Decrease runoff from disturbed areas by using structures to temporarily divert and/or dissipate surface runoff from undisturbed areas.
- Retain sediment within the disturbed areas by using silt fencing, retention ponds, and hay bales.
- Fill pipeline and cable trenches with appropriate material and re-grade surface soon after completion.
- Drainage design will minimize potential for erosion by creating slopes less than 4 to 1 and/or provide rip-rap or other soil stabilization controls.
- Construct roads using techniques that will minimize erosion, such as surfacing with a gravel road base, constructing stream crossings at right angles with adequate embankment protection and culvert installation.
- Use a spill prevention and cleanup plan to minimize soil contamination from vehicle accidents and/or wellfield spills or leaks. Collect and monitor soils and sediments for potential contamination including areas used for land application of treated wastewater, transport routes for yellowcake and ion exchange resins, and well field areas where spills or leaks are possible.

5.8.4 Proposed Mitigation Measures for Surface Water Impacts from the Proposed Action

Potential surface water impacts due to storm events during all phases of the Proposed Action include increased sedimentation and changes in water quality. The following procedures will be used to minimize the impacts to surface waters as discussed in Section 5.7.5.1:

- Minimize disturbance of surface areas and vegetation which, in turn, will minimize erosion and run-off rates.
- Minimize physical changes to drainage channels unless changes are made to upgrade drainage.
- Use erosion and run-off control features such as proper placement of pipe, grading to direct run-off away from water bodies, and use of riprap (broken rock and/or concrete) at these intersections to make bridges or culverts more effective, if necessary.
- Use sediment trapping devices such as hay or straw bales, fabric fences, and devices to control water flow and discharges to trap sediments moved by run-off.
- Train employees in the handling, storage, distribution, and use of hazardous materials.
- Maintain natural contours as much as possible, stabilizing slopes and avoiding unnecessary off-road travel with vehicles; maintaining natural contours as much as possible, stabilizing slopes and avoiding unnecessary off-road travel with vehicles.
- Provide rapid response cleanup and remediation capability, techniques, procedures, and training for potential spills.
- The land application of treated waste water will be applied in a manner consistent with local conditions to avoid excess irrigation run-off into surface water.
- Ponds will be designed with underdrains and leak detection systems to detect and mitigate any impact from a potential leak.
- Fueling operations and storage of hazardous materials and chemicals will be conducted in bermed/curbed areas and in a manner that minimizes potential impacts to surface water.
- Prepare and implement a Storm Water Pollution Prevention Plan that is consistent with state and federal standards for construction activities.

- Surface piping will avoid any identified 100-year or 500-year flood plain levels.
- Curbing relevant facilities and structures at CPP to minimize or eliminate escape of process fluids during spills.

Best management practices will be utilized in all phases of the Proposed Action.

5.8.5 Proposed Mitigation Measures for Potential Groundwater Impacts from the Proposed Action

Potential groundwater impacts during all phases of the Proposed Action include the following: groundwater consumption (Section 5.7.6), alteration of ore zone groundwater quality, potential groundwater quality impacts from accidents, potential groundwater impacts from land application , and potential aquifer restoration impacts will be used to minimize the impacts to groundwater as discussed in Section 5.7.5.4: The following is a list of potential mitigation measures for such potential impacts measures to mitigate impacts to groundwater.

- Minimize groundwater use during operations.
- Monitor well pressures to detect leaks.
- Install monitoring wells as an early warning system for potential lixiviant excursions or leaks from the relevant CPP or SF.
- Maintain pumping and injection rates (well field balance) to ensure radial hydraulic flow into and through the production zone.
- Monitor to detect and define unanticipated surface spills, releases, or similar events that may infiltrate into the groundwater system.
- Implement a spill prevention and cleanup plan to minimize impacts to groundwater, including rapid response cleanup and remediation capability, techniques, procedures, and training.
- Recycle groundwater collected for use in dust suppression and other activities.
- Monitor closest private domestic, livestock, and agricultural wells as appropriate during operations.
- Provide alternate sources of water to landowners in the event of significant drawdown impacts from the proposed action, to domestic wells adjacent to the PAA.
- Select restoration method to minimize water consumption during groundwater restoration.
- Monitor area downgradient from land application sites to determine potential vertical and lateral seepage.
- During restoration, monitor groundwater using standard industry practices to determine the progression and effectiveness of restoration.

5.8.6 Proposed Mitigation Measures for Potential Ecological Resources Impacts from the Proposed Action

Potential ecologic impacts during all phases of the Proposed Action ISL operations could include the following: impacts to vegetation (Section 5.7.8.1), such as alteration of vegetative density, reduction of wildlife habitat, reduction of livestock forage, and changes in visual aesthetics; impacts to wildlife and fisheries (Section 5.7.8.2), such as, loss of habitat, increased soil erosion and human contact; potential impacts to threatened and endangered, or candidate species and species tracked by SDNHP (Section 5.7.8.3), such as, increased human presence and disturbances, and lost of habitat: The following is a list of proposed mitigation measures for such potential impacts:

- Fencing designed to permit big game passage to the extent practicable.

- Use existing roads when possible, and limit construction of new primary and secondary roads to provide for to access to more than one drill site, if possible.
- Enforced speed limits to minimize collisions with wildlife, especially during the breeding season.
- Adherence to timing and spatial restrictions within specified distances of active raptor nests during the breeding season as determined by appropriate regulatory agencies, (February 1 – July 31).
- If direct impacts to raptors or other migratory bird species of concern occur a Monitoring and Mitigation Plan for those species will be prepared and approved by the USFWS, including one or more of the following provisions:
  - Relocation of active and inactive raptor nests that could be impacted by construction or operation activities in accordance with the approved raptor monitoring and mitigation plan
  - Creation of raptor nests and nesting habitat through enhancement efforts such as nest platforms to mitigate other nest sites impacted by ISL operations
  - Obtaining appropriate permits for all removal and mitigation activities
  - Establishing buffer zones protecting raptor nests where necessary and restricting ISL-related disturbances from encroaching within buffers around active raptor nests from egg-laying until fledging to prevent nest abandonment, or injury to eggs or young
  - Reestablishing the ground cover necessary to attract and sustain a suitable raptor prey base after drilling, construction, and future ISL operations and site D&D
  - Required use of raptor-safe construction for overhead power lines according to current guidelines and recommendations by the USFWS
- Restoration of pre-ISL native habitats for species that nest and forage in those vegetative communities.
- Restoration of diverse landforms, direct topsoil replacement, and the construction of brush piles, snags, and/or rock piles to enhance habitat for wildlife.
- Conduct weed control as needed to limit the spread of undesirable and invasive, non-native species on disturbed areas.

Adjusting the timing of various construction, operational, and D&D activities to avoid the breeding season can also be an effective way to minimize impacts related to such activities in the PAA. As a practical matter, worker crews conducting construction or D&D activities only work during daylight hours; so, potential impacts to year-round residents, particularly more nocturnal species such as bats, rodents, and others should not be increased significantly. Following completion of construction in a given area, access roads would be blocked with berms or fencing to prevent use by casual traffic. Site D&D, including surface reclamation will be completed in the same manner, with activities timed to minimize disturbance to nesting or migrating species. Relevant agency standards for reclamation will be followed and this phased, systematic approach will allow more mobile wildlife species to relocate into adjoining, undisturbed habitat and then return following completion of construction or D&D in a particular area. Thus, the sequential, phased nature of this approach will decrease potential direct and indirect impacts on all wildlife species and their habitat.

5.8.7 Proposed Mitigation Measures for Potential Air Quality Impacts from the Proposed Action

Potential impacts to air quality during all phases of the Proposed Action (Section 5.7.9) include the generation of non-radioactive particulate emissions and fugitive dust. Typical air quality protection measures that will be implemented at the project site may include the following:

- Reduce fugitive dust emissions via standard dust control measures (e.g., water application, speed limits).
- Reduce maximum fugitive dust by coordinating dust-producing activities during construction.

- Maintain vehicles to meet applicable EPA emission standards.
- Use of a Yellow Cake vauum dryer virtually eliminates to assure compliance with 40 CFR Part 190.

These proposed mitigation measures will reduce fugitive dust to levels equal to or less than current conditions and ensure that applicable emission standards will be met.

5.8.8 Proposed Mitigation Measures for Potential Noise Impacts from the Proposed Action

Potential noise impacts during all phases of the Proposed Action (Section 5.7.10) include the generation of noise resulting from operating heavy equipment and process machinery. Noise from process machinery will be contained within process structures and, as such, should have no discernible impacts on the public or the environment. With respect to potential noise impacts from heavy equipment, typical mitigation measures that will be implemented at the project to minimize noise impacts may include the following:

- Avoid construction activities during the night.
- Use sound abatement controls on operating equipment and facilities.
- Use personal hearing protection for workers in any high noise areas.

These proposed mitigation measures will ensure that noise levels will remain within relevant EPA guidelines for off-site receptors and OSHA standards for workers.

5.8.9 Proposed Mitigation Measures for Potential Historic and Cultural Resources Impacts

Potential impacts to historical and cultural resources could occur during construction and operations (Section 5.7.11 Mitigation measures that will be implemented at the project site to minimize impacts to historical and cultural resources may include the following:

- Consultation with appropriate SHPO and THPO.
- A Memorandum of Agreement (MOA) has been negotiated and executed with the State of South Dakota Archaeologist to ensure the preservation of any historical, cultural, and archaeological sites that may be present within the PAA. Additional MOA mitigation measures have been prepared to ensure that no significant historical, cultural, or archaeological resources will be damaged during all phases of the Proposed Action.
- Conduct pre-construction surveys to ensure that work will not affect important historical, cultural, and archaeological resources.
- NRC License Conditions mandating phased identification of previously unidentified historical, cultural or archaeological resources and immediate response procedures for protecting such resources during all phases of the Proposed Action.

5.8.10 Proposed Mitigation Measures for Potential Visual/Scenic Resources Impacts

Potential impacts to visual/scenic resources (Section 5.7.12) during all phases of the Proposed Action include the alteration of visual/scenic resources. Typical visual/scenic mitigation measures that could be implemented at the project site include the following:

- Use exterior lighting only where needed to accomplish facility tasks.
- Limit the height of exterior lighting units.
- Use shielded or directional lighting to limit lighting only to areas where it is needed.

- Construction and placement of structures taking into consideration the topography in order to conceal wellheads, plant facilities, and roads from public vantage points.
- Satisfy BLM guidelines by using building materials and paint that complement the natural environment.
- During construction of roads, consider the topography that a given road follows, as well as the potential area of disturbance.

5.8.11 Proposed Mitigation Measures for Potential Socioeconomic Impacts from the Proposed Action

As discussed in Section 5.7.13, the overall impacts of the proposed project indicate that the project will result in positive socioeconomic benefits to the local and regional economy, with the potential to create of hundreds of jobs and millions of dollars in tax revenue. The potential impacts of increased population associated with the project are expected to be dispersed, due to the remoteness of the PAA and the phased nature of construction, operation, and site D&D. The proposed mitigation measures to minimize adverse socioeconomic impacts include the following:

- Use local vendors, employees, and contractors to the extent possible.
- Develop and deliver educational presentations and tours to interested groups in nearby communities to maintain community awareness of the nature of the Proposed Action.

5.8.12 Proposed Mitigation Measures for Potential Environmental Justice Impacts from the Proposed Action

As discussed in Section 5.7.14, the Proposed Action will not have any significant adverse impacts and, therefore, will not have significant disproportionate impacts on minorities or low-income individuals as compared with the state-wide averages; therefore, no mitigation measures need to be identified.

5.8.13 Proposed Mitigation Measures for Potential Public and Occupational Health Impacts from the Proposed Action

Potential impacts to pubic and occupational health (Section 5.7.15) during all phases of the Proposed Action include potential exposure to hazardous chemicals and radiological emissions such as radon-222. The proposed mitigation measures for potential public and occupational health impacts from the PA include the following:

- Use downflow, pressurized IX columns, and ventilation during resin transfers to keep occupational exposure to radon levels in process facilities as low as is reasonable achievable (ALARA).
- Use vacuum dryers, bag filters, and vapor filtration to reduce particulate emissions during yellowcake drying.
- Use high-efficiency particulate air filters or similar controls for all particulates.
- Design SOPs to reduce potential accidents.
- Implement health and safety procedures and administrative controls to minimize workers risks during all phases of the PA.
- Develop and implement training programs for Powertech (USA) personnel to enable them to respond to all potential emergencies.
- Develop emergency management procedures/SOPs that are consistent with standard and best management practices to satisfy applicable non-radiological exposure limits and to implement risk control recommendations contained in NUREG/CR-6733 analyses.

- Installation of engineering and administrative controls consistent with standard and best management practices to prevent both surface and subsurface releases to the environment, and to mitigate the effects in the event of an accident.

5.8.14 Proposed Mitigation Measures for Potential Waste Management Impacts from the PA

Potential impacts from waste management activities (Section 5.7.15.5) during all phases of the PA include potential exposure to hazardous and radiological emissions from such wastes. The proposed mitigation measures for potential impacts associated with waste management activities from the Proposed Action include the following:

- Recycle wastewater to reduce the amount of water needed for facilities and the amount of wastewater that could require disposal
- Use decontamination techniques that reduce waste generation
- Institute preventative maintenance and inventory management programs to minimize waste from breakdowns and overstocking
- Recycle non-radioactive materials where appropriate
- Encourage the reuse of materials and use of recycled materials
- Avoid using hazardous materials when possible
- Develop a spill prevention plan for petroleum products and other hazardous materials
- Ensure that equipment is available to respond to spills and identify the location of such equipment
- Inspect and replace worn or damaged components
- Salvage extra materials and use them for other construction activities or for regrading activities
- Install curbs or berms on all waste storage areas
- Install leak detection and warning systems in all liquid waste facilities

5.8.15 Proposed Mitigation Measures for Potential Impacts from Uncontaminated Solid Waste Management

The PA will generate non-radioactive (i.e., uncontaminated) solid wastes, which could include, but are not limited to: fluorescent tubes, and light ballasts, batteries not directly associated with uranium recovery, and waste paper, cardboard and other materials generally associated with office and equipment maintenance activities. These materials will be collected on a regular basis and disposed of in an appropriately permitted off-site disposal facility.

5.8.16 Proposed Mitigation Measures for Potential Impacts from 11e.(2) Byproduct Material Management

Byproduct material requiring offsite disposal in accordance with NRC requirements and/or license conditions will be transported off-site to an NRC-approved disposal facility. Powertech (USA) estimates that the PA will produce approximately 100-yd^3 of 11e.(2) byproduct material per year. These materials will be stored on-site to prevent any potential release, will be properly labeled, and will be isolated inside the restricted area until such time as a full shipment can be transferred to an NRC-approved disposal site.

5.8.17 Proposed Mitigation Measures for Potential Impacts from Hazardous Waste Management

The potential exists for any industrial facility to generate hazardous waste as defined by the Resource Conservation and Recovery Act (RCRA). On the basis of the processes and materials proposed to be used for the PA, it is likely that this project will be classified as a CESQG (a generator that generates less than 100 kg of hazardous waste in a calendar month) and will comply with all applicable hazardous waste program requirements. Powertech (USA) expects that only used waste oil and universal hazardous wastes such as cleaning solvents and spent batteries will be generated at the project. Powertech will develop management programs to meet the regulatory requirements for a CESQG. However, in the event it is not classified as a CESQG, Powertech (USA) will dispose of such wastes in a manner consistent with applicable regulations and requirements.

POWERTECH (USA) INC.

Section 6.0 - Interim Management Plan

6.1 Background

The Interim Management Plan was developed in compliance with Section 3809.401 of Title 43 CFR. The plan addresses management upon temporary closure and prevention of undue and/or unnecessary deterioration of facilities.

6.2 Reasons and Causes of Temporary Closure

Powertech's Dewey-Burdock Proposed Action has an expected mine life of 17 years based on the estimated time it would take to mine out and process the total inferred resources of 10.8 million lbs listed in the company's 43-101. As further exploration is performed, additional resources may be delineated for mining, thus extending the life of mining. Various reasons may exist for temporary closures throughout the life of the mine:

- Uneconomical mining environment i.e. uranium price drop and/or mining costs increase.
- Lack of adequate manpower to operate the mine safely and efficiently.
- Road closures due to weather or other causes.
- Inadequate ore reserves or grade resulting in additional exploration activities prior to advanced development.
- Loss of ore purchase agreement.

If for any reason a temporary closure results, the following will be implemented.

6.3 Measures to Stabilize Excavations and Workings

There are no underground workings associated with an ISL mine. The surface area will be maintained according to the project's Storm Water Management Plan (SWMP). Areas experiencing erosion and/or runoff will be monitored periodically in accordance with the approved SWMP and POO. All drainage features will be inspected periodically and cleaned and maintained as necessary. Reclamation will proceed as weather permits.

6.4 Measures to Isolate or Control Toxic or Deleterious Materials

Potentially toxic materials on site are limited to, fuel and oil, water treatment chemicals, and possibly a solvent cleaning station in one or two maintenance shops. Measures for isolating or controlling each of these materials during temporary closure are described below.

As discussed above, reclamation and restoration would continue during a short-term closure.

During short-term closure, fuel tanks, oils and other petroleum products will be secured in a locked area and solvents will be gathered and disposed of by a licensed vendor. Inspections will be performed for all secured areas and secondary containment features onsite. These areas will be maintained in such a manner so operations could resume at any time.

However, if a closure were to extend into a six month time frame, Powertech would evaluate other control methods, such as implementation of an alternative treatment system and/or adjusting surface reclamation efforts. Based on previous experience, there are several options available to operators with regard to conducting reclamation and restoration safely and efficiently in a manner that is protective of health and environment. All fuels and oils will be removed from the site upon a long-term closure.

Adequate pond and tank capacity will be maintained in order to treat and/or store water and manage the site in the case of precipitation that may contribute to runoff in a magnitude such as the 100 year, 24 hour storm event.

ISL operations do not create ore stockpiles, however if Powertech is in possession of an amount of loaded resin that meets the capacity of licensed conditions, Powertech will attempt to transport the resin for processing within six months of a temporary closure. If for some reason this cannot be accomplished within six months, Powertech will work with appropriate agencies to develop a long-term material storage plan. The plan may include utilizing a building on site as a secured storage area with appropriate safety controls, alarms and locks. Additional monitoring may be required.

6.5 Provisions for the Storage or Removal of Equipment, Supplies and Structures

Equipment and supplies will be maintained on site in secure areas during a short-term closure period. Vehicles associated with onsite work will be locked and parked within a secure gated area. Most supplies and equipment will remain stockpiled in the yard area or under lock and key in the maintenance shops, and the warehouse. A security guard will be present on site as needed to deter theft and vandalism.

If period of closure extends to six months, Powertech may gradually remove some or all equipment, supplies, and both mobile and modular structures from the site to minimize potential for vandalism and theft; this measure would also reduce the need for fulltime security personnel. The equipment and supplies would be moved to other property under Powertech's control.

6.6 Measures to Maintain the Project Area in a Safe and Clean Condition

The Safety and Environmental Review Panel (SERP) will conduct a review every quarter during a temporary closure to ensure safety and environmental procedures are conducted appropriately and demonstrate compliance with applicable license and permit requirements.

Good housekeeping standards and practices will be practiced in all areas of the site this requires areas to be kept clean and free of litter and debris. Trash, used tires, old equipment parts, empty barrels, and other miscellaneous materials will be removed from the site and either recycled or disposed of properly as general housekeeping and surface reclamation continue throughout the temporary closure. Site safety will be maintained by discouraging unauthorized access through the use of locked gates, fences, warning signs, and security personnel. All buildings and trailers will be kept locked when not in use. The gates to the main facilities area, CPP and SF areas, and will also be locked.

6.7 Plans for Monitoring Site Conditions During Periods of Non-Operation

During temporary closure, environmental monitoring will continue as required by the various licenses and permits. This will include monitoring of:

- Discharges of treated water
- Monitoring wells
- Personnel
- Storm water

All surface areas will be inspected at least weekly during a closure of six months or less. If the site remains relatively stable and the closure period extends beyond six months, the frequency of surface inspections may be reduced.

6.8 Closure Schedule and Reporting

No seasonal or maintenance shutdowns of the project are anticipated at this time. In the event that market conditions or other circumstances require a temporary shutdown of mine operations, Powertech will provide notice to the BLM within 30 days after such suspension in compliance with Part 3802.4-7 of Title 43 of the CFR. This notice will include:

- Verification of intent to maintain structures, equipment, and other facilities
- The expected reopening date
- Current mine contact information
- Any revisions to this Interim Management Plan

Section 7.0 - Geology and Hydrology

7.1 Regional Structure and Stratigraphy

The project is located in the Great Plains Physiographic province on the southwestern flank of the Black Hills uplift in southwestern South Dakota. To the west of the PAA is the Powder River Basin of Wyoming. The regional geologic map of this region is shown in Figure 7.1-1.

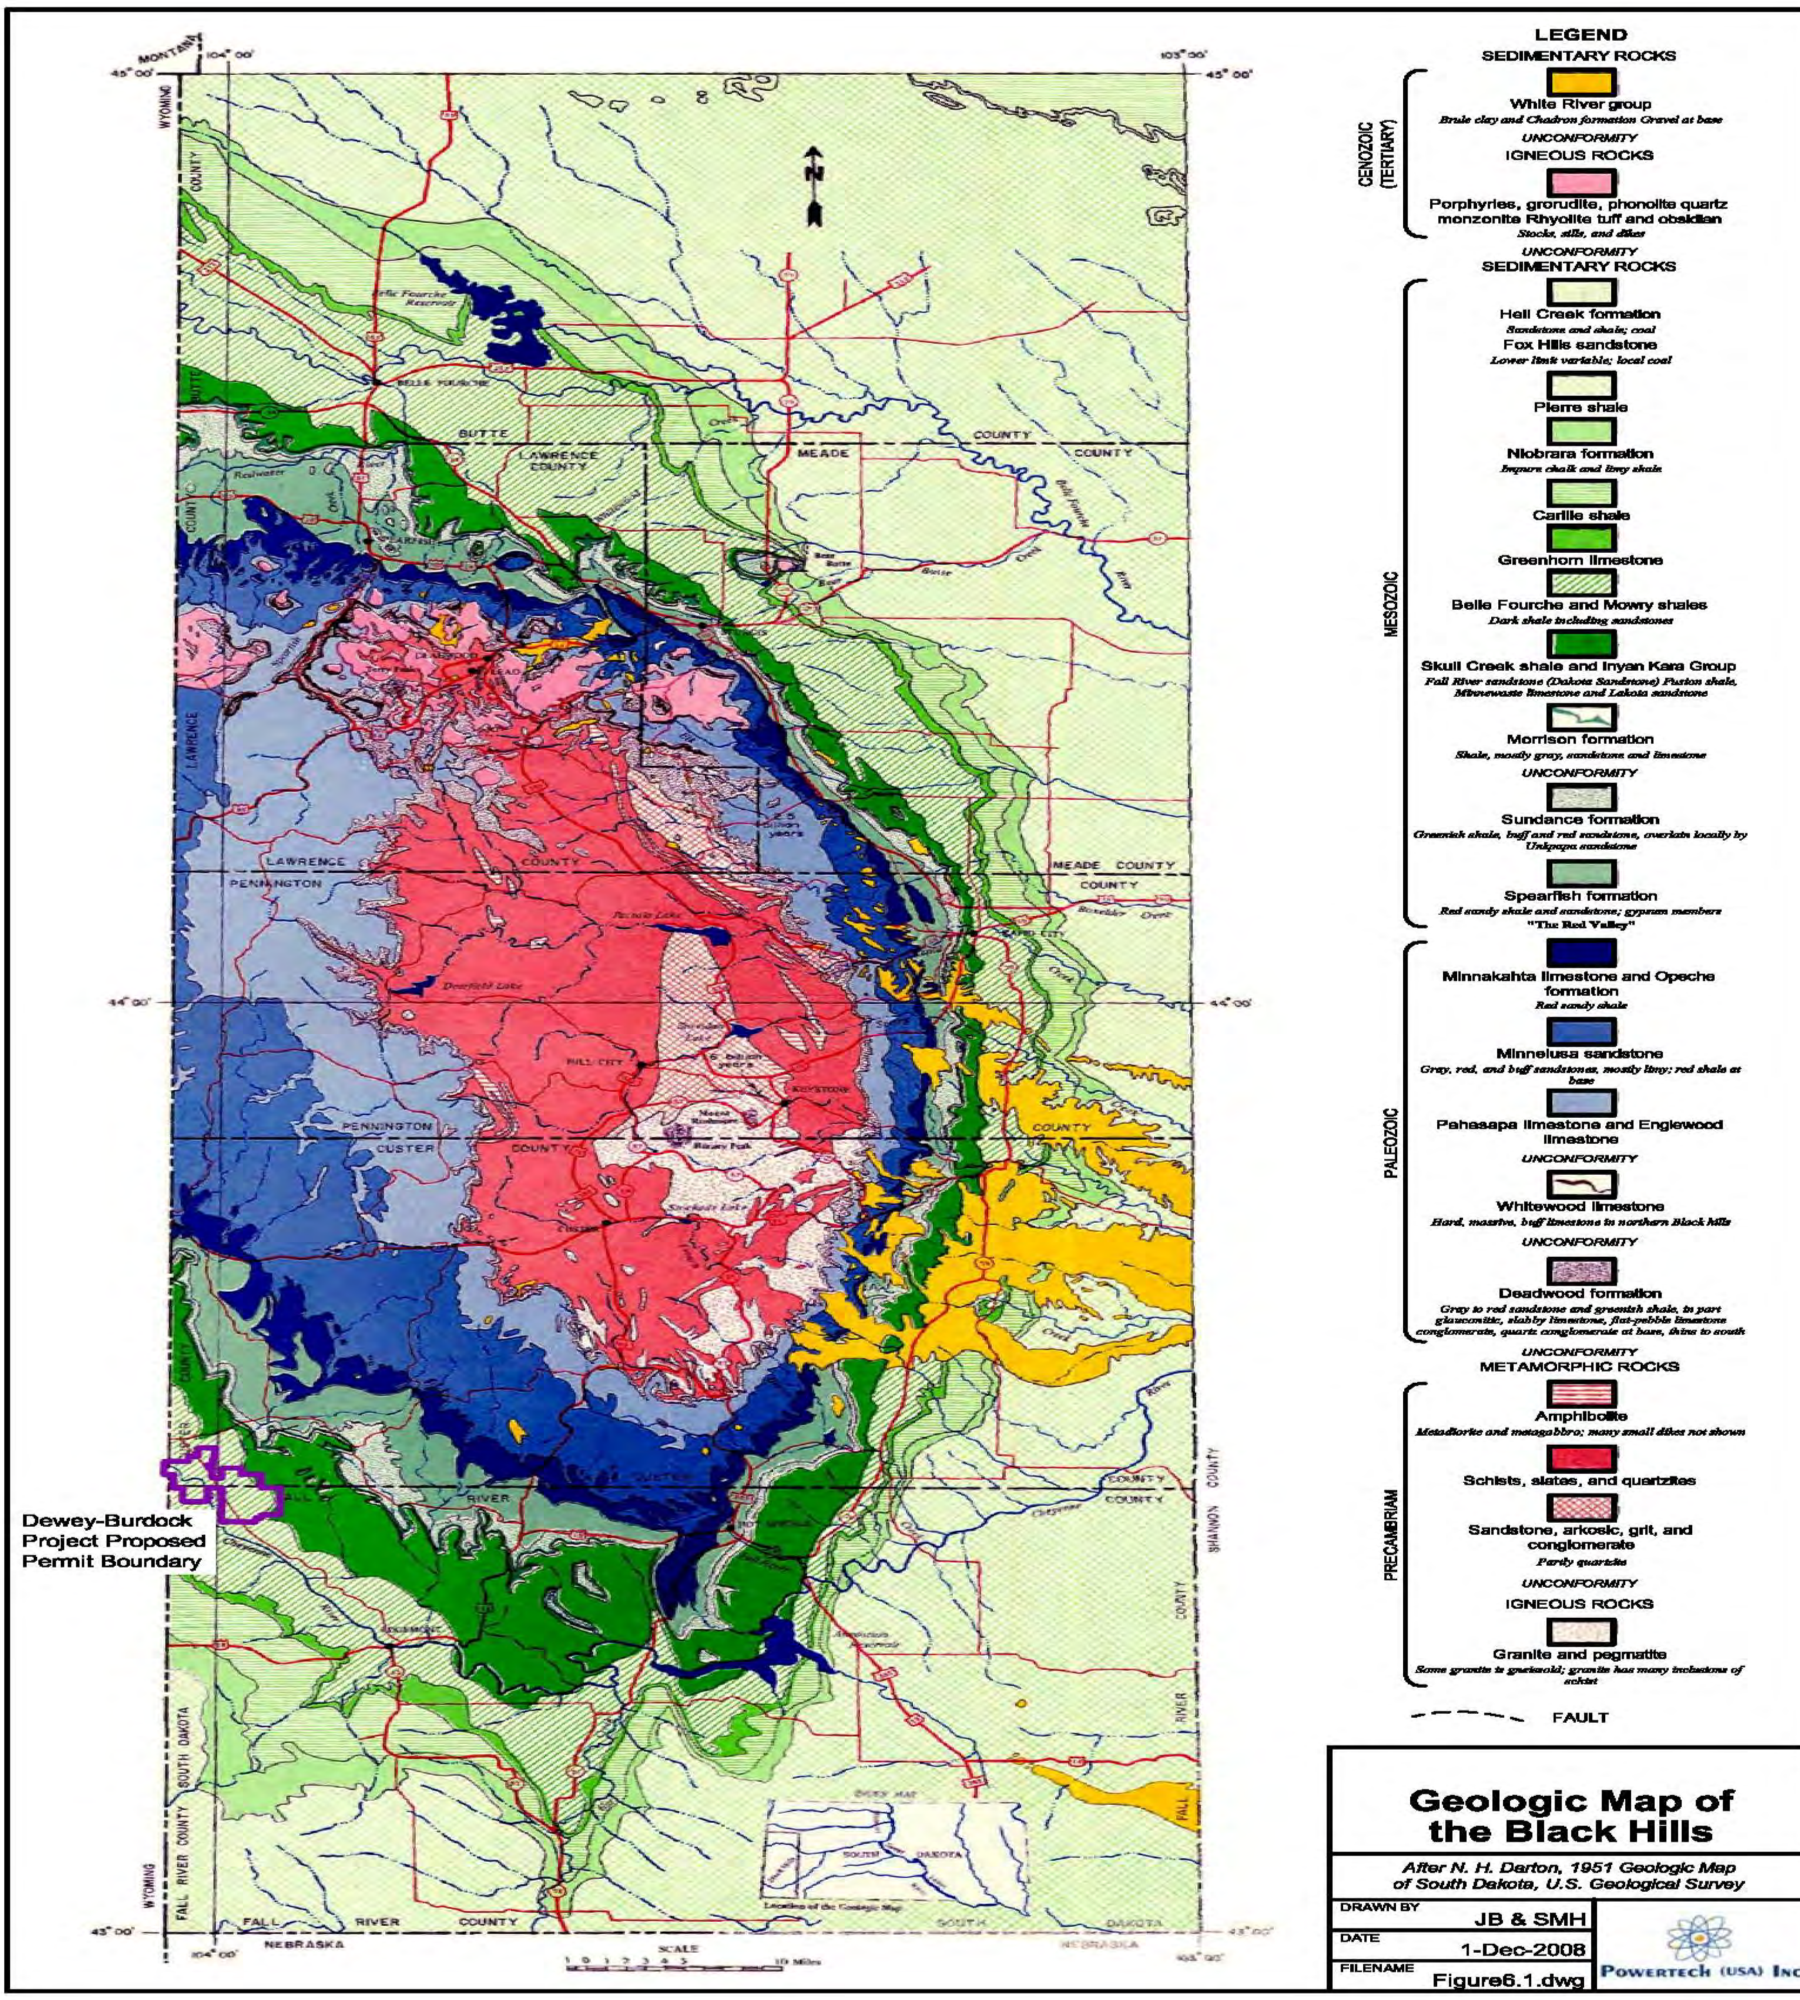

Figure 7.1-1 Geologic Map of the Black Hills

7.1.1 Regional Structure

The dominant structural feature in this region is the Black Hills Uplift. This uplift is of Laramide age (65 million years ago) and is an elongate northwest trending dome about 125 miles long and 60 miles wide. Igneous and metamorphic Precambrian-age rock are exposed in the core of the uplift and are surrounded by outward-dipping Paleozoic and Mesozoic rocks that form cuestas and hogbacks around the core of the uplift. Folds constitute the major structural features in the Black Hills. In early Cretaceous time minor deformation along concealed northeast trending structures of Precambrian age affected the courses of the northwest flowing streams and their tributaries, thereby influencing the location of the fluvial sandstone deposits of the Inyan Kara Group.

7.1.2 Regional Stratigraphy

The oldest rocks in the region are Precambrian metamorphic rocks and granites. These form the core of the Black Hills Uplift and are exposed at the surfaced of this structural feature. Overlying these crystalline rocks are 2000-3000 feet of Paleozoic sediments. This sedimentary sequence contains several regional aquifers, to include the Deadwood Formation of Cambrian age, the Mississippian Madison Limestone and the Pennsylvanian/Permian-age Minnelusa Formation.

Mesozoic sediments include the Triassic age Spearfish Formation and the Sundance, Unkpapa and Morrison Formations of Jurassic age. The Sundance Formation is a minor aquifer in the southern Black Hills region. A thick sequence of Cretaceous age sediments completes the Mesozoic section.

The Early Cretaceous sediments of the Inyan Kara Group consist of the Lakota Formation and the Fall River Formation and is a transitional unit, exhibiting a change from terrestrial to marine deposition. The basal Lakota Formation (Chilson Member) is a fluvial sequence, which grades upward into marginal marine sediments as the Cretaceous Seaway inundated a stable land surface. Basal units of the Lakota Formation scour into clays of the underlying Morrison Formation and display the depositional nature of a large braided stream system, crossing a broad, flat coastal plain and flowing toward the northwest. Younger fluvial sand units of the Lakota become progressively thinner and less continuous and are separated by thin deposits of overbank and flood plain silts and clays. At the top of the Lakota is the Fuson Member. The Fuson consists of shale with minor beds of fine grained sandstone and siltstone. The Fuson separates the underlying Lakota Formation from the overlying Fall River Formation. The Fall River consists of thick, widespread fluvial sands in the lower portion, grading to thinner, less continuous, marginal sands in the upper part. The Cretaceous Lakota and Fall River Formations are the hosts of the roll front uranium mineralization in the Black Hills region.

Following deposition of the Fall River, this region was covered by the North American Cretaceous Seaway, which resulted in the accumulation of vast thicknesses of marine sediments. From 3000-5000 feet of these marine sediments are represented by the Skull Creek Shale, Newcastle Sandstone, Mowry Shale, Belle Fourche Shale, Greenhorn Formation, Carlisle Shale, Niobrara Formation and Pierre Shale. In Late Cretaceous time, the modern Rocky Mountain Uplift began, forcing the retreat of the Cretaceous seaway.

Unconformably overlying the Cretaceous sediments in the Black Hills region is the Tertiary-age (Oligocene) tuffaceous White River Formation. This thick, tuffaceous sequence was the result of volcanic eruptions to the west and was rich in volcanic fragments. The White River sediments have primarily been removed by erosion and can be found only as erosional remnants. This unit is thought to be the source of the uranium deposits found in the Black Hills region and the Powder River Basin of Wyoming.

The most recent sediments in the region are Quaternary-age deposits consisting of local material derived as a result of post-Laramide-uplift erosion. Recent deposits include alluvium and floodplain terrace deposits. Refer to Figure 7.1-2 for a stratigraphic column of the Black Hills.

Powertech (USA) Inc.

Figure 7.1-2 Stratigraphic Column of the Black Hills Area

7.2 Site Structure and Stratigraphy

The site geology is shown in Figure 7.2-1. The Fall River Formation outcrops across the eastern part of the project and the Skull Creek Shale and Mowry Shale outcrops across the western part of the project. The formations dip west and southwest at 2 to 6 degrees.

The geology of the project was developed through the interpretation of data gathered from thousands of exploration drill holes. For each drill hole there was a suite of down-hole electric logs run to characterize natural radioactivity and the lithology (rock type) of the sediments in the subsurface. Resistivity and Self Potential provide the rock types encountered in the subsurface (sandstone, siltstone, shale, etc.). This is further enhanced by a geologist's description of the drill cuttings. Exhibit 7.2-1 is an example of a "type log" from the project.

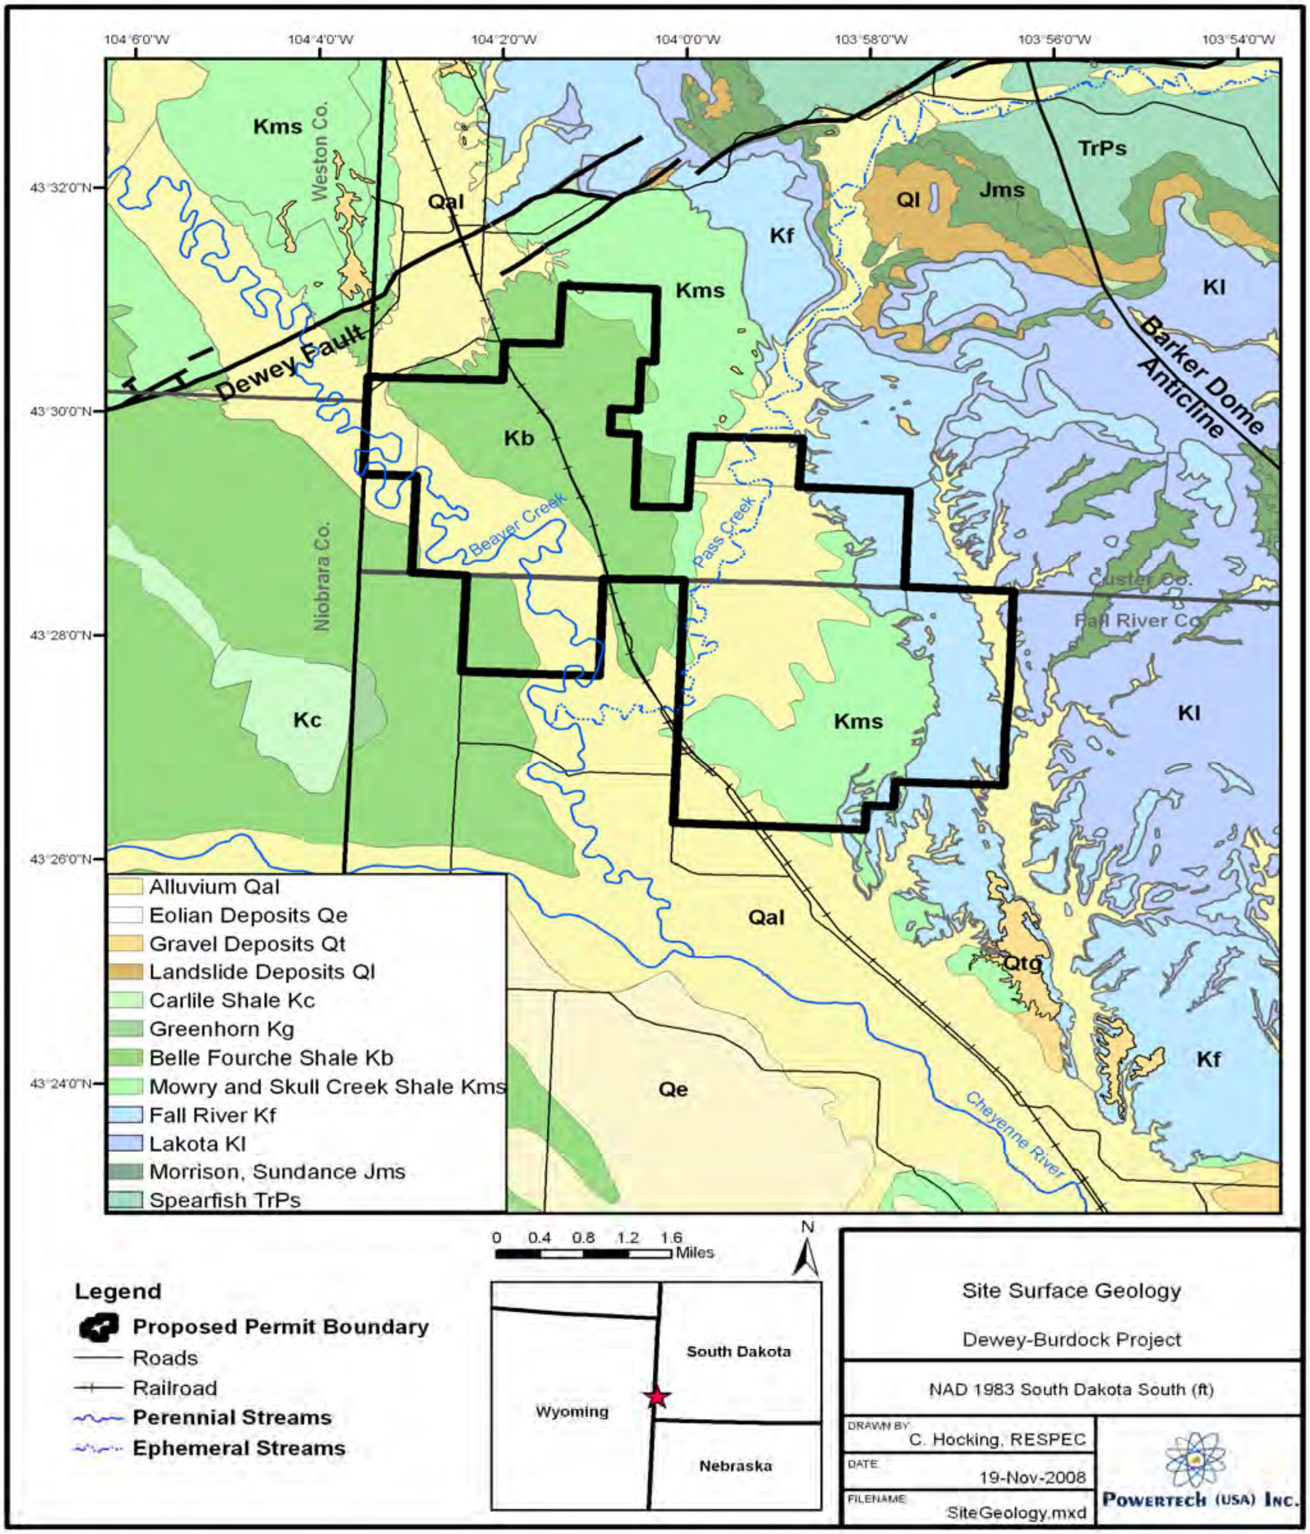

Figure 7.2-1 Site Surface Geology

7.2.1 Site Structure

The structure across the project is simple and shows sediments dipping gently 2 to 6 degrees to the southwest. This is illustrated by a structure contour map on the tops of the Fall River Formation (Exhibit 7.2-2) the Chilson Member of the Lakota Formation (Exhibit 7.2-3) and the Unkpapa Formation (Exhibit 7.2-4).

The Dewey Fault, a northeast to southwest trending fault zone, is present approximately one mile north of the north and northwest parts of the PAA. The Dewey Fault is a steeply dipping to vertical normal fault with the north side uplifted approximately 500 feet by a combination of displacement and drag. The USGS considers an area 7 miles southeast of the project as the Long Mountain Structural Zone. This northeast – southwest trend contains several small shallow surface faults in the Inyan Kara. No faults show up along this trend on subsurface structure maps of the underlying Madison Formation, Minnelusa Formation or the Deadwood Formation. Despite the presence of faulting north and south of the site, there are no identified faults within the Dewy-Burdock PAA.

There is some folding in the areas surrounding the project. East of the project is a northwest – southeast trending anticline that ends in a closed structure called the Barker Dome. To the west is the Fanny Peak Monocline. This monocline is the structural boundary between the Black Hills and the Powder River Basin.

7.2.2 Site Stratigraphy

The sedimentary rocks of primary interest that underlie the project range in age from Upper Jurassic to Early Cretaceous. The Upper Jurassic Morrison Formation is considered to be the Lower Confining Unit for the project. The uranium mineralization is contained within the Inyan Kara Group (Lakota and Fall River Formations). The Skull Creek Shale is the Upper Confining Unit. Exhibit 7.2-5 is a generalized cross section of the PAA, illustrating the relationship between these sedimentary units, as well as their position to underlying rocks, ranging in age from Jurassic to Precambrian.

The following is a brief description of the formations of interest at the project site:

Morrison Formation - The Upper Jurassic Morrison Formation was deposited as flood plain deposits. It is composed of waxy, unctuous, calcareous, noncarbonaceous massive shale with numerous limestone lenses and a few thin fine grained sandstones. Below the site, this formation has an average thickness of approximately 100 feet and is the Lower Confining Unit for the project. Analyses of core samples demonstrate that the Morrison clays have extremely low vertical permeabilities, ranging from 3.9×10^{-9} cm/sec to 4.2×10^{-8} cm/sec (0.004 millidarcies to 0.043 millidarcies).

Inyan Kara Group – This Group consists of the Lakota Formation and the Fall River Formation. Sandstones within these two formations are hosts to all the uranium mineralization for the project.

Lakota Formation - The Lakota Formation consists of three members; from lower to upper are the Chilson Member, the Minnewasta Limestone Member and the Fuson Member.

The Minnewasta Limestone Member is not present in the PAA.

The Chilson Member (commonly referred to as the Lakota Sandstone) is composed largely of fluvial deposits. These deposits consist of sandstone, shale, siltstone, and shale. The member consists of a complex of channel sandstone deposits and their laterally fine-grained equivalents. The Chilson Member consists of two units; a basal carbonaceous black mudstone and an overlying unit of channel sandstones with laterally fine-grained equivalents and interbedded shales. The sandstones are very fine to medium-grained and well sorted and were deposited by a northwest flowing river system. Analyses of core samples of these sandstones indicate these units exhibit high horizontal permeabilities, ranging from

2.6×10^{-3} cm/sec to 4.1×10^{-3} cm/sec (2697 millidarcies to 4161 millidarcies). The massive sandstone is made up of numerous individual sand filled channels, which contain the uranium deposits.

The isopach map of the Chilson Member of the Lakota Formation shows the thickness of the channel sandstones and interbedded shales within the Chilson Member. Thicknesses vary from 100 to 240 feet. This isopach map may not adequately show the total thickness of the Chilson Member because drilling usually did not penetrate its entire extent. Drilling was usually stopped in the lower carbonaceous shale unit of the Chilson Member and did not reach the Morrison Formation. (Exhibit 7.2-6)**.**

The Fuson Member is the upper most member of the Lakota Formation and the shale-siltstone portion of the Fuson has been used to divide the Lakota Formation from the Fall River Formation. Analyses of core samples of these lithologies demonstrate low vertical permeabilities, ranging from 7.8×10^{-9} cm/sec to 2.2×10^{-7} cm/sec (0.008 millidarcies to 0.228 millidarcies).

The Fuson Member is described as having a lower discontinuous sandstone unit at its base and an upper discontinuous sandstone at the top of the member. If present the lower sandstone unit was mapped as Lakota sandstone. Similarly if the upper sandstone was present it was mapped as Fall River sandstone. The isopach map of the Fuson Member shows the thickness of the shale – siltstone unit ranging from 30 to 80 feet (Exhibit 7.2-7). It shows thinning of the shale under the overlying channel sandstones of the Fall River Formation.

Fall River Formation - The Fall River formation is composed of carbonaceous interbedded siltstone and sandstone, channel sandstones, and a sequence of interbedded sandstone and shale. The lower part of the Fall River consists of dark carbonaceous siltstone interbedded with thin laminations of fine-grained sandstone. Channels were cut into this interbedded sequence by northwest flowing rivers and fluvial sandstones were deposited. These channel sandstones occur across various parts of the project and generally contain the uranium deposits. Overlying the channel sandstones is another sequence of alternating sandstone and shales. The sandstones are cross-bedded to massive, fine to medium-grained, and well-sorted.

The isopach map of the Fall River Formation shows a range of thickness of 120 to 160 feet. The thickening of the formation indicates the presence channel sandstones. Along the northeastern portion of the PAA, this formation is exposed on the surface and erosion has taken place (Exhibit 7.2-8)**.**

Skull Creek Shale - The Skull Creek Shale directly overlies the Fall River Formation and consists of dark-grey to black shale, organic material, and some silt sized quartz grains. The Skull Creek Shale has a thickness of approximately 200 feet and is the Upper Confining Unit for the project. Analyses of core samples demonstrate that the Skull Creek clays have extremely low vertical permeabilities, in the range of 6.8×10^{-9} cm/sec (0.007 millidarcies). The Skull Creek Shale is eroded from the eastern parts of the project.

Mowry Shale – At the project the Skull Creek Shale is directly overlain by the Mowry shale and is also considered to be part of the Upper Confining Unit. Normally, the Newcastle Sandstone is present between the Skull Creek Shale and the Mowry Shale, but is absent across the PAA. The Mowry Shale consists of light gray marine shale with minor amounts of siltstone, fine grained sandstone, and a few thin beds of bentonite. Dark-gray to purple and black iron and manganese concretionary zones are common within the shale. The combined Skull Creek Shale – Mowry Shale reaches a thickness of 400 feet in the western part of the project. Exhibit 7.2-9 is an isopach map showing the combined thickness of these two shale units. In the northeastern portion of the PAA, these units outcrop and have been eroded.

Terrace Deposits - Along the sides of drainages are relatively flat terrace deposits representing floodplains and former levels of streams. The terraces are primarily overbank deposits of clay and silt with gravel beds. Gravel deposits consist of boulders and pebbles of chert, sandstone, and limestone.

Alluvium - The most recent sedimentary units deposited within the PAA are the Quaternary age alluvium deposits. Alluvium is present in the major drainages and their tributaries. The alluvium consists of silt, clay sand and gravel.

Four site cross sections, based on exploration logs, were developed along each orebody to illustrate the relationship between mineralized Inyan Kara sands and their confining units. Exhibit 7.2-10 shows the locations of the four cross sections. The cross sections were generated in the MVS model and were hung on the elevation of each drill hole. Traces of electric logs of exploration holes were overlain on these cross sections to illustrate the data sources used in the preparation of these sections. Cross sections A-A'', F-F', H-H''', and J-J' show the project stratigraphy and mineralization across the PAA and are presented in Plates 7.2--11, 7.2-12, 7.2-13, and 7.2-14. The Skull Creek Shale thickens from the east to the west. The Fall River Formation is continuous across the area and dips to the west. The Fuson Member of the Lakota thickens and thins across the area. The Chilson Member of the Lakota is continuous across the area and thickens and thins due to channeling. The uranium mineralization in the Fall River occurs in the lower sandstone unit. The mineralized sands in the Chilson Member of the Lakota occur within individual sandstone lenses or channels.

7.3 Ore Mineralogy and Geochemistry

Uranium deposits within the project are classic, sandstone, roll-front type deposits, similar to those in Wyoming and Texas. These type deposits are usually "C" shaped in cross section, with the concave side of the deposit extending up-dip, toward the outcrop. Roll-front deposits are a few tens of feet-to-100 or more-feet wide and often thousands of feet long. Uranium minerals were emplaced in these deposits after migrating down gradient from the surface in oxygenated groundwater and precipitating in the subsurface upon encountering a reducing environment at depth. These roll-front deposits are centered at and follow the interface of naturally-occurring chemical boundaries between oxidized and reduced sands. Reducing conditions are the result of a reductant in the sands these can be from organic material or from Hydrogen Sulfide (H_2S) or methane in the host sands.

There is a geochemical "footprint" associated with these roll-front deposits, resulting from the passage of oxygenated groundwater through subsurface sands. The typical alteration pattern associated with these oxidizing solutions consists of limonitic and hematitic staining of the sandstones. This is due to the alteration of naturally-occurring iron rich minerals (valence state of Fe^{+2}) to iron oxides (valence state of Fe^{+3}). On outcrop, most of the sandstones of the Inyan Kara Group exhibit trace to pervasive limonite staining of various shades of yellow and orange. Red hematite staining is less common and occurs as scattered streaks in most outcrops. Generally, the more porous and thicker the sandstone, the more pronounced the alteration. Reduced or unaltered sands have a medium to dark grey color. Alteration within the host sands has been mapped for distances of over 12 miles within the sandstones of the Inyan Kara Group in the PAA.

The primary uranium minerals in the project deposits are very fine-grained, opaque pitchblende and coffinite. This mineralization occurs as sand grain coatings in the host sand, and marginal to or as replacement of pyrite grains.

Mineralized sands within the project occur at depths of less than 100 feet in the outcrop area of Fall River Formation and at depths of up to 800 feet in the Lakota in the northwest part of the project. This mineralization occurs in three sandstones in the Fall River Formation and within six sandstones of the Lakota Formation. The uranium mineralization occurs along a large "U" shaped trend that is five miles long and three to four miles wide. The average thickness of this mineralization has been calculated to be 6.1feet and the average grade is 0.21 percent U_3O_8.

In 1988 in a Thesis for a Master of Science in Geology degree, Bonnie Janine Blake used scanning x-ray fluorescence supplemented by standard x-ray fluorescence, x-ray diffraction, electron microprobe, scanning electron microscopy, and atomic absorption to study core samples from the Burdock orebody.

She did not identify any uranium or vanadium minerals but concluded that the uranium was in an amorphous or poorly-crystalline form or was associated with the clays or carbonaceous material. Bonnie Blake noted “quartz grains illustrated layered clay coatings in the paragenetic sequence of a smectite partially covered by kaolinite with remnants of possible illite on the kaolinite. The smectite coatings showed isolated concentrations of uranium and vanadium.” This is to be expected where uranium cation exchanges with the clays. The uranium mineralization is probably uranphane and coffinite.

7.4 Historic Uranium Exploration

Uranium was first discovered in the Edgemont District in 1952 by professors from the SDSMT. They mined about 500 pounds of ore and hauled it to Grand Junction, Colorado. The Atomic Energy Commission (AEC) announcement of a new district at Edgemont led to a boom of stacking, mining, and dealing in the summer of 1952. By 1953 the AEC had built a buying station in Edgemont. In July 1956 a 250-ton per-day mill went on stream and soon expanded to a 500-ton-per-day. In 1960 a vanadium circuit was added. Production from the Edgemont District (open pits in the Fall River), some mines in the Powder River basin and several mines in the Northern Black Hills continued until 1972. Susquehanna Western Inc. (SWI) bought the Edgemont mill and took control of the mines in the Edgemont District. Until the late 1960’s early 1970’s they were the only company active in the Edgemont District.

In 1967, Homestake Mining Company began exploration in the Dewey area. In 1974, Wyoming Mineral Corporation (Westinghouse) acquired the Dewey properties from Homestake. In 1974, TVA bought out the mill and mines from SWI. The mill was shut down, but exploration continued. Besides WMC and TVA, other companies exploring in the district were Union Carbide, Federal Resources, and Kerr McGee. TVA acquired the Dewey Project from WMC in 1978 and continued exploration until 1986. In total, over 4000 exploration drill holes were completed on this project.

In 1981 TVA completed a mine feasibility study on the project deposits. A DES was prepared by TVA to address the potential impacts of a proposed underground mine in the PAA, but the NEPA process was never completed by TVA. Due to falling uranium prices the project leases were allowed to expire. In 1994 EFN acquired the mineral interests within the PAA. Their intention was to mine the uranium deposits by ISL. EFN did no additional exploration drilling on the project. In 2000 the leases were dropped.

In 2005, Powertech (USA) acquired the property, consisting of approximately 10,580 acres. Since the spring of 2007, Powertech (USA) has drilled approximately 115 exploration holes, including 20 monitoring wells on the project. Both the historic and recent drill holes have helped to generate the geologic mode and delineate the extent of the mineralized sands. Figure 7.4-1 is a map showing the location of all known drill holes. Appendix 7.4-A includes a table summarizing all historical exploration drilling.

POWERTECH (USA) INC.

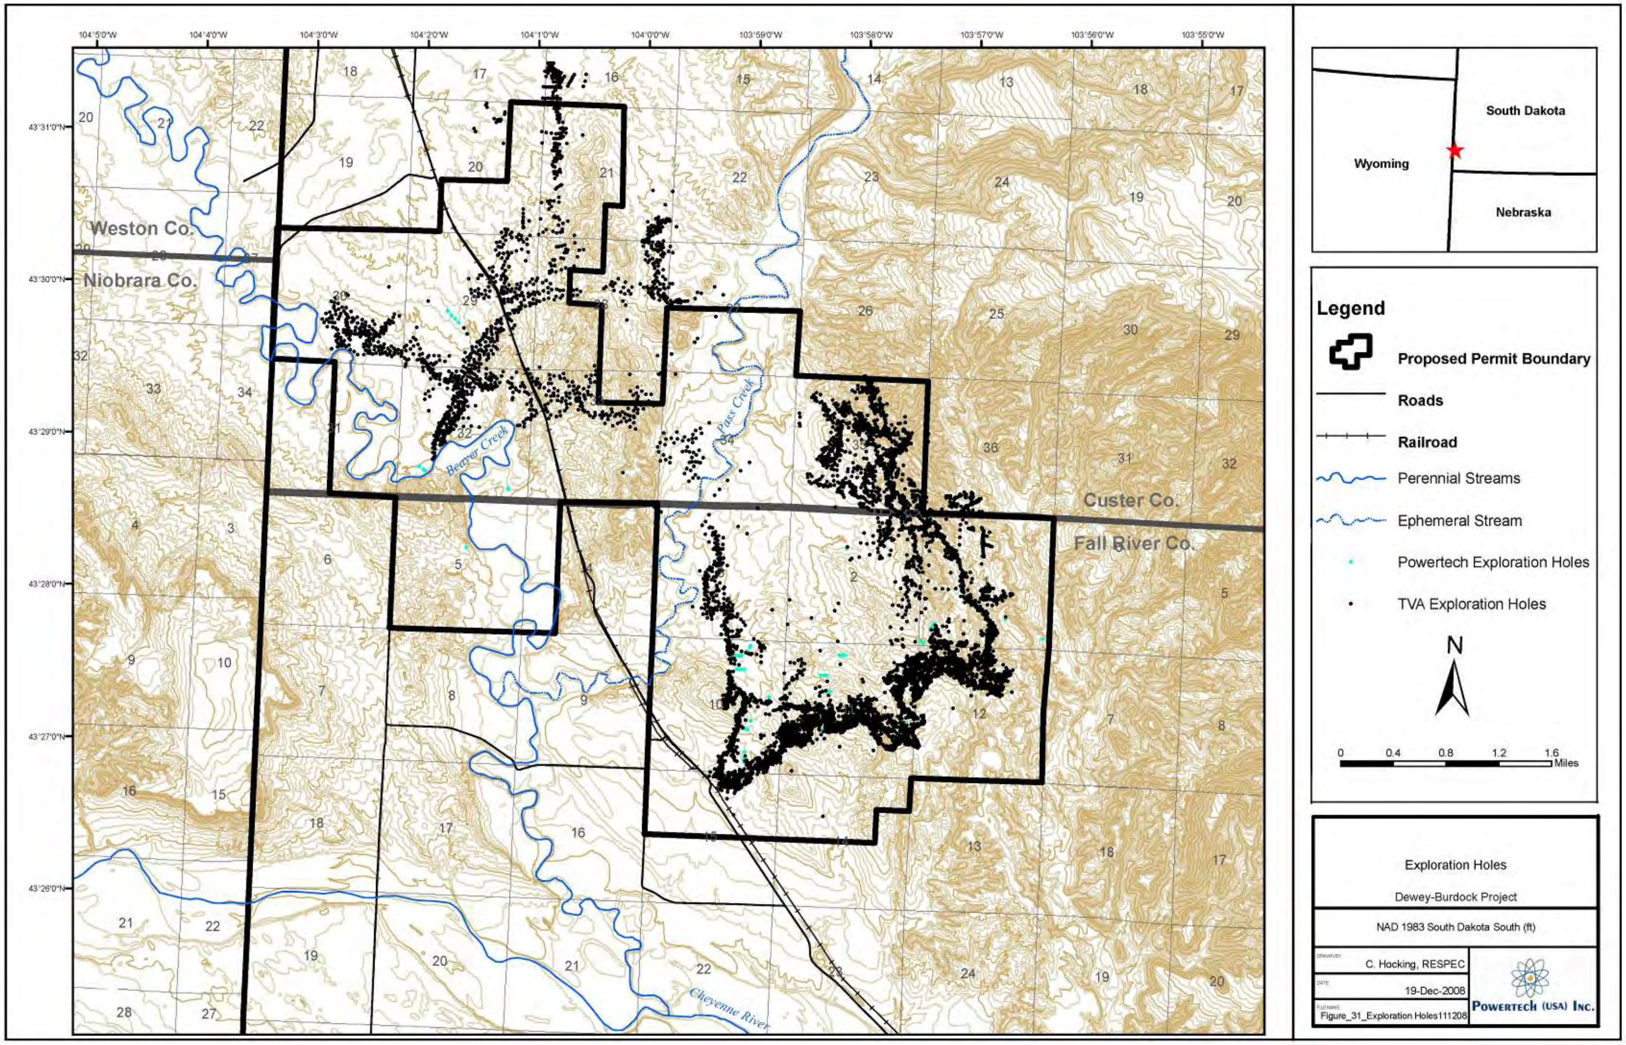

Figure 7.4-1 Location of all Known Exploration Drill Holes within the Proposed Project Site

7.5 Soils

Powertech (USA) conducted baseline soil sampling and mapping covering an estimated 7,964.26 acres as shown on Exhibit 7.5-1 in accordance with NUREG-1569 and RG-4.14.

Stripping depths for the PAA were evaluated during mapping and sampling. Soil depths within a given mapping unit will vary based on any combination of the five primary soil forming factors, i.e., climate including effective precipitation, organisms, relief or topography, parent material, and time. Subtle differences in any one of the previously mentioned factors will impact development between series and within series designation but may not be as noticeable as when topography is a major factor. The proposed topsoil salvage depths are based on laboratory data of the samples found within the borders of the area, as well as field observations and knowledge of the soils in Custer and Fall River Counties, South Dakota.

Soils in the PAA are typical for semi-arid grasslands and shrublands in the Western United States. Parent material included colluvium, residuum, and alluvium. Most soils are classified taxonomically as Aridic Argiustolls, Aridic Ustorthents, and Aridic Haplusterts.

Almost all soils have some suitable topsoil. The primary limiting factors within the PAA are electrical conductivity (EC), sodium adsorption ratio (SAR), calcium carbonates, and texture (clay percentage).

Refer to Appendix 7.5-A for the Soil Mapping Unit Descriptions. Refer to Appendix 7.5-B for the Soil Series Descriptions. Refer to Appendix 7.5-C for the Original Laboratory Data Sheets. Refer to Appendix 7.5-D for the Prime Farmland Designation. Refer to Appendix 7.5-E for the Site Photographs.

7.5.1 Methodology

7.5.1.1 Review of Existing Literature

The soils in this portion of Custer and Fall River Counties were studied and mapped to an Order 2 scale by the USDA, NRCS in 1982 and 1990. Information for Custer and Fall River Counties is available electronically as well as hard copy. The NRCS has also centralized dissemination of typical soil series descriptions; general information is available on the internet at www.nrcs.usda.gov.

7.5.1.2 Project Participants

BKS performed the 2007 soil survey field work and compiled the resulting report. All soil analysis was handled by Energy Labs in Gillette, Wyoming.

7.5.1.3 Soil Survey

Construction of the PAA soil map was completed according to techniques and procedures of the National Cooperative Soil Survey. Guideline No. 1 (August, 1994 Revision) of the WDEQ-LQD was followed during all phases of the work.

A total of 7,960.77 acres were included in the final soil mapping of the PAA, in which 3,065.74 of those acres were located in disturbance areas. Refer to Table 7.5-1 for soil mapping unit designations and associated acreage within the PAA. Table 7.5-1 also describes the soil map units in terms of actual map designations and slope percentages.

7.5.1.4 Field Sampling

Soil series were sampled to reflect recommended sample numbers in WDEQ Guideline 1 (August 1994 Revision) based on mapping acreage. Most samples were taken either in or near disturbed areas.

Table 7.5-1 Proposed Action Area Soil Mapping Unit Acreages

Map Symbol	Map Unit Description	Permit Acreage	Disturbance Areas	% Total PAA

Additional sampling of soils in the permit area will occur as the operation is expanded outside the current disturbed areas.

Series were sampled and described by coring with a mechanical auger, i.e., truck-mounted Giddings. The physical and chemical nature of each horizon within the sampled profile was described and recorded in the field. Each hole augered for series and map unit verification was plotted on the soils map included with this report. Sampled soil material was placed in clean, labeled, polyethylene plastic bags and kept cool to limit chemical changes. Samples were kept out of direct sunlight and transported to Energy Labs for analysis. A total of 33 sites on the PAA were sampled for analysis; all had corresponding soil profile descriptions written. Refer to Table 7.5-2 Soils Series Sample Summary and Table 7.5-3 Soil Sample Locations.

[1]Samples were taken within proposed disturbed area as defined by initial estimates of the orebody.

7.5.1.5 Laboratory Analysis

Samples were individually placed into lined aluminum pans to air dry. Coarse fragments were measured with a 10 mesh screen prior to grinding; the entire sample was then hand ground to pass 10 mesh. An approximate 20 ounce subsample was obtained through splitting with a series of riffle splitters and subsequently analyzed. A second subsample was maintained in storage at Energy Labs. Approximately 10 percent of the samples are run for duplicate analysis. Actual laboratory analysis follows the methodology outlined in WDEQ-LQD Guideline 1 (August 1994 Revision). In general, samples were analyzed within 45 days of receipt of the samples at the laboratory. All analytical data is presented in Appendix 7.5-C, Original Laboratory Data Sheets.

7.5.2 Results and Discussion

7.5.2.1 Soil Survey - General

General topography of the area ranged from nearly level uplands to very steep hills, ridges and breaks of dissected shale plains. The soils occurring on the PAA were generally a clayey or very fine texture throughout with patches of sandy loam on upland areas and fine, clay textured soils occurring in or near drainages. The PAA contained deep soils on level upland areas with shallow and very shallow soils located on hills, ridges and breaks.

7.5.2.2 Soil Mapping Unit Interpretation

The primary purpose of the 2007 fieldwork was to characterize the soils within the PAA in terms of topsoil salvage depths and related physical and chemical properties. The total number of samples per series was established in line with WDEQ Guideline 1 (August 1994 Revision) recommendations based on estimated acreage of soil series known within the PAA. Refer to Appendix 7.5-A and Appendix 7.5-C for soil mapping unit descriptions and soil series descriptions, respectively.

7.5.2.3 Analytical Results

Analyzed parameters, as defined in WDEQ Guideline 1 (August 1994 Revision), are in Appendix 7.5-C Original Laboratory Data Sheets. Laboratory soil texture analysis did not include percent fine sands. Field observations of fine sands within individual pedestals as well as sample site topographic position were used in conjunction with laboratory analytical results to determine series designation. Where applicable, field observation of fine sands is also included in the textures found in the soil series descriptions in Appendix 7.5-D. In several of the pedestal sampling locations, laboratory analysis yielded finer than expected textures (based upon field observations). Where textures are finer than typical for the series, it is noted in the Range of Characteristics (according to field observations, lab analysis) in the soil series descriptions.

7.5.2.4 Evaluation of Soil Suitability as a Plant Growth Medium

Approximate salvage depths of each map unit series are presented in Table 7.5-4 and ranged from 0.0 to 5.0 feet. Within the PAA, suitability of soil as a plant growth medium is generally affected by physical factors such as texture (clay percentage) and saturation percentage. Chemical limiting factors included selenium (Se), calcium carbonate content (based upon field observations of strong or violent effervescence), SAR, EC, pH, and boron (B). Marginal material, according to WDEQ Guideline 1, was found in 26 of the 33 profiles. Unsuitable material, according to WDEQ Guideline 1, was found in 14 of the 33 profiles. Marginal or unsuitable parameter information for sampled profiles is identified in Table 7.5-5. A summary of trends in marginal or unsuitable parameters as it relates to soil series is found in Table 7.5-6. Based on laboratory analysis and field observations, marginal material parameters primarily consisted of texture (clay percentage), calcium carbonates, EC, and SAR.

7.5.2.5 Topsoil Volume Calculations

Based on the 2007 fieldwork with associated field observations and subsequent chemical analysis, the recommended topsoil average salvage depth over the PAA was determined to be 1.43 feet. Refer to Table 7.5-4, Approximate Soil Salvage Depths.

7.5.2.6 Soil Erosion Properties and Impacts

Based on the soil mapping unit descriptions, the hazard for wind and water erosion within the PAA varies from negligible to severe. The potential for wind and water erosion is mainly a factor of surface characteristics of the soil, including texture and organic matter content. Given the very fine and clayey texture of the surface horizons throughout the majority of the PAA, the soils are more susceptible to erosion from water than wind. See Table 7.5-7 for a summary of wind and water erosion hazards within the PAA.

Table 7.5-7 Proposed Action Area Summary of Wind and Water Erosion Hazards[1]

Soil Sample Number	Map Unit Description	Water Erosion Hazard	Wind Erosion Hazard
17	Broadhurst silty clay, 6 to 15 percent slopes	slight	very slight
27	Kyle noncalcareous variant, 0 to 6 percent slopes	moderate	very slight
36	Kyle noncalcareous variant, 0 to 6 percent slopes	moderate	very slight

7.5.2.7 Prime Farmland Assessment

Prime farmland was assessed by Dan Shurtliff, the Acting State Soil Scientist out of Huron, South Dakota. The following sections in T6S R1E contain Prime farmland if irrigated: Sections 27, 30, 31, 32, 34, and 35. The following sections in T7S R1E contain Prime farmland if irrigated: Sections 1, 3, 4, 5, 10, 12, 14, and 15. The following sections in T7S R1E contain Farmland of statewide importance: Sections 2, 3, 4, 5, 10, 11, 12, 14, and 15. See Appendix 7.5-D for prime farmland designation. The following soil series have been listed as Prime farmland if irrigated: Alice, Ascalon, Barnum, Boneek, Haverson, Norka, Nunn, Satanta, and Tilford. The following soil series have been listed as Farmland of statewide importance: Kyle, Lohmiller, Nunn, Pierre, Satanta, and Stetter.

7.6 Seismology

7.6.1 Seismic Hazard Review

The seismic hazard review was based on analysis of available literature and historical seismicity for the PAA. 10 CFR Part 40, Appendix A Criterion 4(e) states:

"The impoundment may not be located near a capable fault that could cause a maximum credible earthquake larger than that which the impoundment could reasonably be expected to withstand. As used in this criterion, the term "capable fault" has the same meaning as defined in section III (g) of Appendix A of 10 CFR Part 100. The term "maximum credible earthquake" means that earthquake which would cause the maximum vibratory ground motion based upon an evaluation of earthquake potential considering the regional and local geology and seismology and specific characteristics of local subsurface material."

There are no capable faults (i.e. active faults) with surface expression mapped within a radius of 100 kilometers (62 miles) from the center of the PAA, according to the 2002 U.S. Geological Survey's Quaternary Fault and Fold Database. In addition, there are no capable faults mapped in the entire state of South Dakota. The closest capable faults to the site are located in central Wyoming, nearly 345 km (200 miles) to the west-southwest.

7.6.2 Seismicity

South Dakota has a comparatively higher rate of seismicity than other areas in the northern plains states, although earthquakes in the area tend to be relatively rare and of low to moderate magnitude, and no active faults have been mapped in the vicinity. It is unclear which earthquakes, if any, in the PAA are associated with known faults. Since the Midwestern states are relatively stable in terms of earthquake activity, only a small number of seismograph stations are located in the region. South Dakota has one station located in Rapid City, which began operation in 1991. Two nearby stations are located in Golden, Colorado and French Village, Missouri.

Since 1872, a minimum of 65 earthquake epicenters have been identified in South Dakota (Hammond, 1992). These hfave mainly been concentrated in the southern and eastern regions of the state and are generally of low to moderate modified Mercalli intensity, with a maximum recorded intensity reaching VI. In general, the majority of the epicenters in the proximity of the project (see Figure 7.6-1) exhibit modified Mercalli intensities from III to V (corresponding to Richter magnitudes ranging from 2.2 to 4.1). However, a 1966 earthquake with intensity VI (approximate Richter magnitude 4.4) was recorded approximately 63 miles northeast of the project (17 miles northwest of Rapid City).

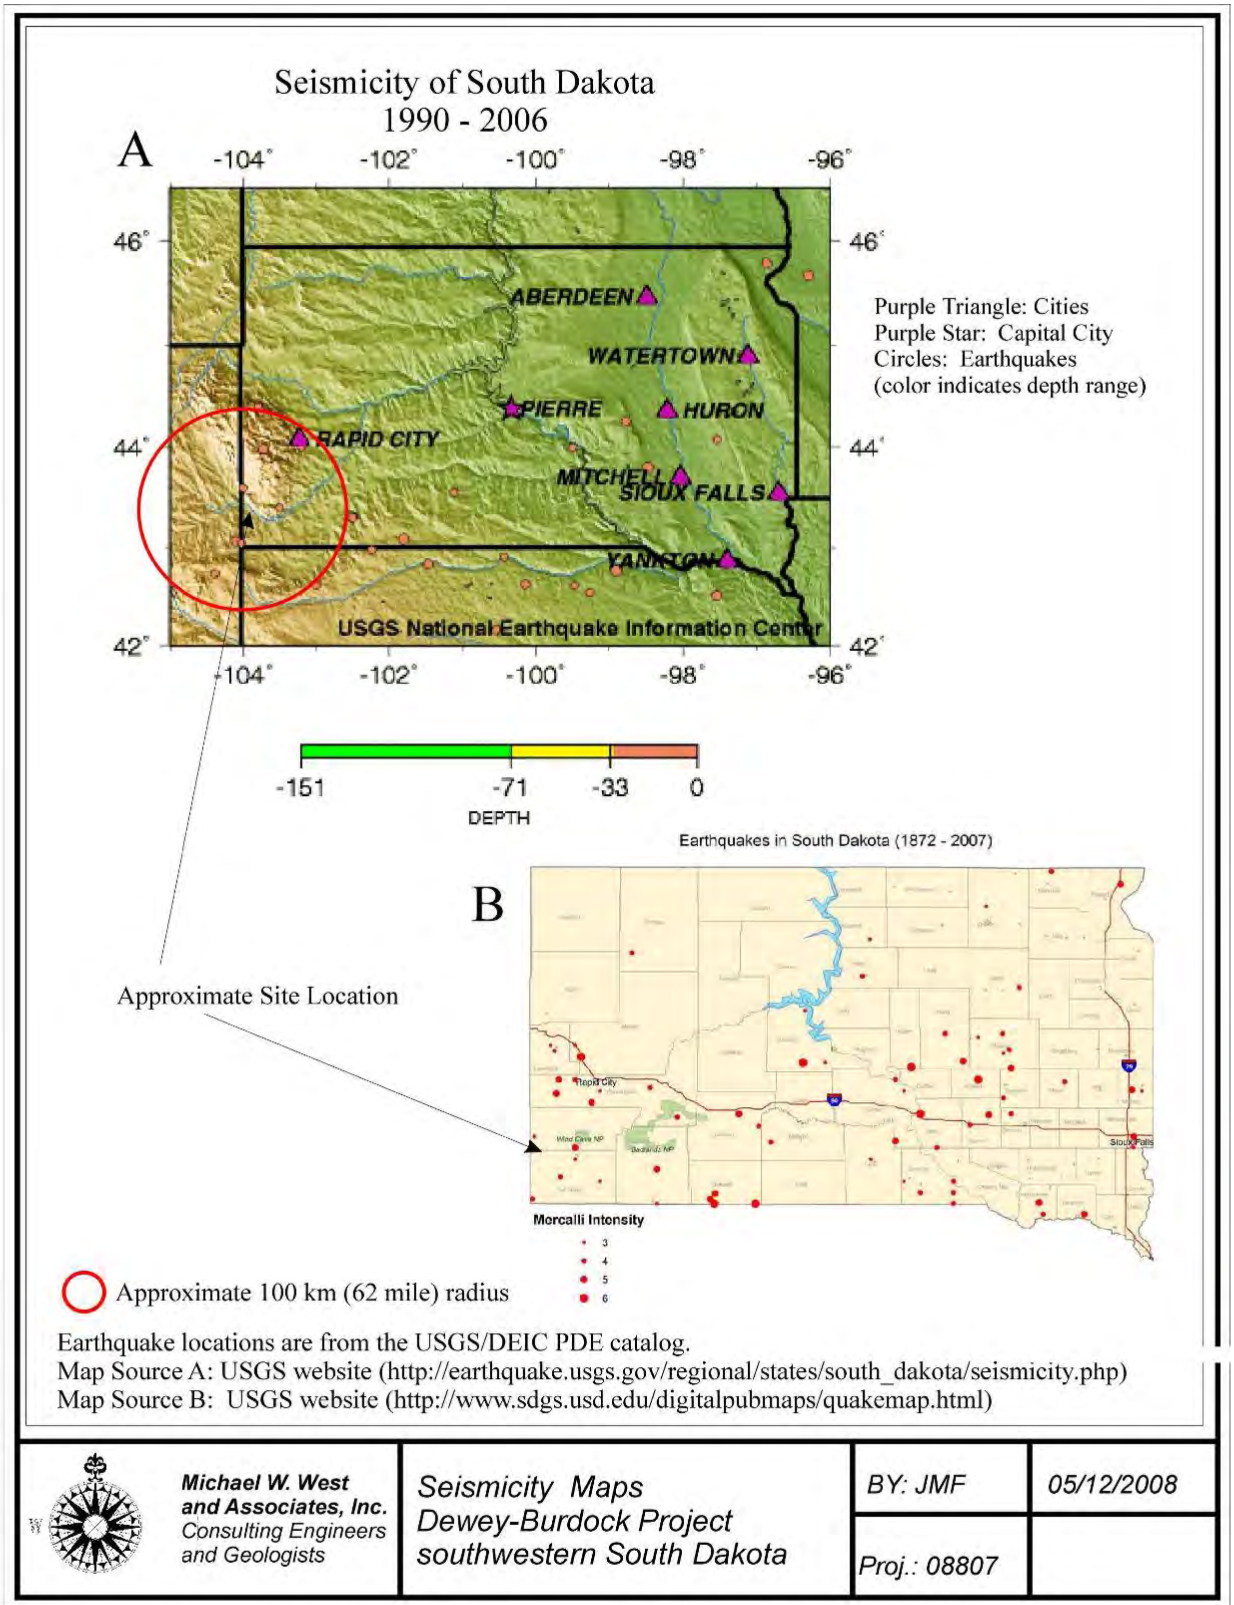

Figure 7.6-1 Seismicity of South Dakota, 1990 – 2006; and Earthquakes in South Dakota, 1872-2007

The U.S. Geological Survey Earthquake Database reports locations, times, and magnitudes for epicenters recorded since 1973. The database reports a total of 10 earthquakes with Richter magnitudes ranging from 2.3 to 3.7 within 100 km radius of the site (Appendix 7.6-A). This list includes epicenters in Wyoming and Nebraska. The closest historical earthquake to the project site (unknown magnitude) was recorded on May 16, 1975 approximately 19 km (12 miles) southeast of the site. The most recent earthquake recorded in the entire state of South Dakota took place on February 7, 2007, 35 miles east of Rapid City (approximately 80 miles northeast of the project site) and displayed a magnitude of 3.1.

According to the U.S. Geological Survey Earthquake Database (Appendix 7.6-A), two historical earthquakes, each exhibiting a magnitude of 3.7, represent the largest historical events recorded within 100 km (62 miles) of the project. These events occurred on February 6, 1996, and April 9, 1996, and were located 76 km (47 miles) to the north and 30 km (19 miles) to the southwest of the site, respectively. If the search radius was expanded to 200 km (124 miles), an earthquake with magnitude 5.50 occurring on October 18, 1984 approximately 180 km (112 miles) to the southwest of the site is the largest magnitude event near the site.

A zone of higher earthquake frequency is recorded along the eastern flank of the Black Hills (structural deformation also seems to be concentrated on the eastern flank; Geological Survey of South Dakota, 2004) and in the southwest corner of South Dakota (Figure 7.6-2). In addition, the PGA maps (USGS, 2002) of the area display an increase in ground motion to the west and southwest part of the state (Figures 7.6-3). Earthquakes may be concentrating along or near the boundaries of structural provinces (e.g. Black Hills and Missouri Plateau, or Missouri Plateau and High Plains) in the Precambrian, crystalline basement. Two possible faulting mechanisms may be at work: 1) initiation of movement along preexisting fractures due to crustal plate movements; or 2) fault movement and fracturing due to glacial rebound (South Dakota Department of Emergency Management website).

According to the U.S. Geological Survey's 2002 Seismic Hazard Mapping Program, the peak ground acceleration (PGA) derived from the probabilistic maximum bedrock acceleration with a 10 percent exceedance in 50 years (475-year return period) is 0.03 g (Figure 7.6-3) for the southwestern part of South Dakota. The probabilistic maximum bedrock acceleration with a 2 percent chance of exceedance in 50 years (2,475-year return period) is 0.09 g for the region.

Figure 7.6-3 Peak Ground Acceleration (PGA), Illustrating 2 Percent Probability of Exceedance in the Next 50 Years

7.6.3 Seismic Sources

Assessment of seismic hazards requires consideration of potential earthquake source zones, either identifiable faults or larger areas with common seismic characteristics. Once potential source zones have been identified, design earthquakes can be assigned based on a synthesis of geological and seismological data.

7.6.4 Capable Faults

The proposed project is located in an area of historically low seismic potential. There are no known capable faults within 100 kilometers of the site and a relatively low number of historical earthquakes (Appendix 7.6-A). The closest capable fault zone to the project is located nearly 345 km (200 miles) west of the site in central Wyoming. Therefore, the randomly occurring ‘floating’ earthquake is considered to be the most significant seismic hazard for the PAA (discussed below), the same as the maximum credible earthquake as defined in 10 CFR Part 40, Appendix A Criterion 4(e), quoted above.

7.6.5 The Randomly Occurring ‘Floating’ Earthquake

Industry standards and federal regulations require an analysis of the earthquake potential in regions where the surface expression of active faults is not mapped or exposed, and where earthquake epicenters are associated with buried faults with no associated surface rupture. Earthquakes associated with buried faults are assumed to occur randomly and can occur anywhere within that area of uniform earthquake potential. In reality, random earthquake distribution may not be the case, since all earthquakes are associated with specific faults. However, since all buried faults in the PAA have not been identified, it is reasonable to consider the distribution to be random. A ‘floating’ earthquake is an earthquake that is considered to occur randomly within a tectonic province.

The U.S. Geological Survey identified tectonic provinces for the contiguous United States (Algermissen et al., 1982). The project site is located in a source zone with a uniformly distributed seismicity which generally encompasses the Black Hills and surrounding environs. The zone is characterized by an earthquake with maximum magnitude M_{max}=6.1. This magnitude is used as the best estimate for the floating earthquake.

7.6.6 Conclusion

Seismic hazards at the project site include low to moderate ground shaking associated with regional and local earthquake sources. Figures 7.6-1 through 7.6-3 illustrate seismicity and PGA maps for the PAA, and Appendix 7.6-A is a summary of the USGS database results for historical earthquakes recorded within 100 and 200 km from the site since 1973.

There are no capable faults (as defined in section III (g) of Appendix A of 10 CFR Part 100) known to be present within 100 km of the project site. The closest capable fault zone to the project is located nearly 345 kilometers (200 miles) west of the site in central Wyoming. Therefore, the most significant seismic hazard is considered to be the randomly occurring, or ‘floating’, earthquake for the PAA. This is the maximum credible earthquake estimated for the project based on available literature, geologic information of the surrounding area, and historical data. A magnitude M_{max}=6.1 is estimated for this event.

According to the U.S. Geological Survey’s 2002 Seismic Hazard Mapping Program, PGA derived from the probabilistic maximum bedrock acceleration with a 10 percent exceedance in 50 years (475-year return period) is 0.03g (Figure 7.6-2) for the southwestern part of South Dakota. The probabilistic maximum bedrock acceleration with a 2 percent chance of exceedance in 50 years (2,475-year return period) is 0.09g for the region (Figure 7.6-3). Both of these estimates are considered to reflect a relatively low ground motion hazard.

7.7 Regional Surface Water Hydrology

Powertech (USA) conducted baseline surface water and groundwater quality monitoring in accordance with NRC Regulatory Guide 4.14 and NUREG-1569. The following sections describe the hydrology baseline assessment program and results.

7.7.1 Surface Water

7.7.1.1 Regional Hydrology

The PAA is approximately 12 mi^2 and lies in southwestern Custer County and northwestern Fall River County in South Dakota (Figure 7.7-1). Precipitation incorporates both rainfall and snow which can differ greatly based on elevation of the area and time of year. According to historical precipitation data, the upper elevations of the Black Hills can receive up to 24 inches annually, while most of the lower plains receive significantly less (Driscoll and others, 2002).

The PAA is in the Southern Black Hills, which includes two physiographic divisions that are characterized as the Black Hills and the Great Plains Divisions. The Black Hills Division generally consists of steep formations of metamorphosed and intensely compacted sedimentary rocks, which form a perimeter around an intrusion of Precambrian igneous and crystalline rocks. The sedimentary layers consist of aquifer formations that typically have high permeability, which allows for the transportation and storage of water. Aquifers are usually separated by an aquitard layer that restricts the vertical transport of water from one aquifer to the next. The aquifers generally receive a large amount of recharge from stream losses and infiltration. The infiltration rates can vary greatly due to variations in slope and soil and can have a significant impact on the base flow of natural streams (Driscoll and others, 2002).

The Great Plains physiographic division is characterized by relatively flat, rolling hills which are divided by low-sloping streams. The streams generally have well-developed natural drainage areas that primarily flow from west to east (Driscoll and others, 2002).

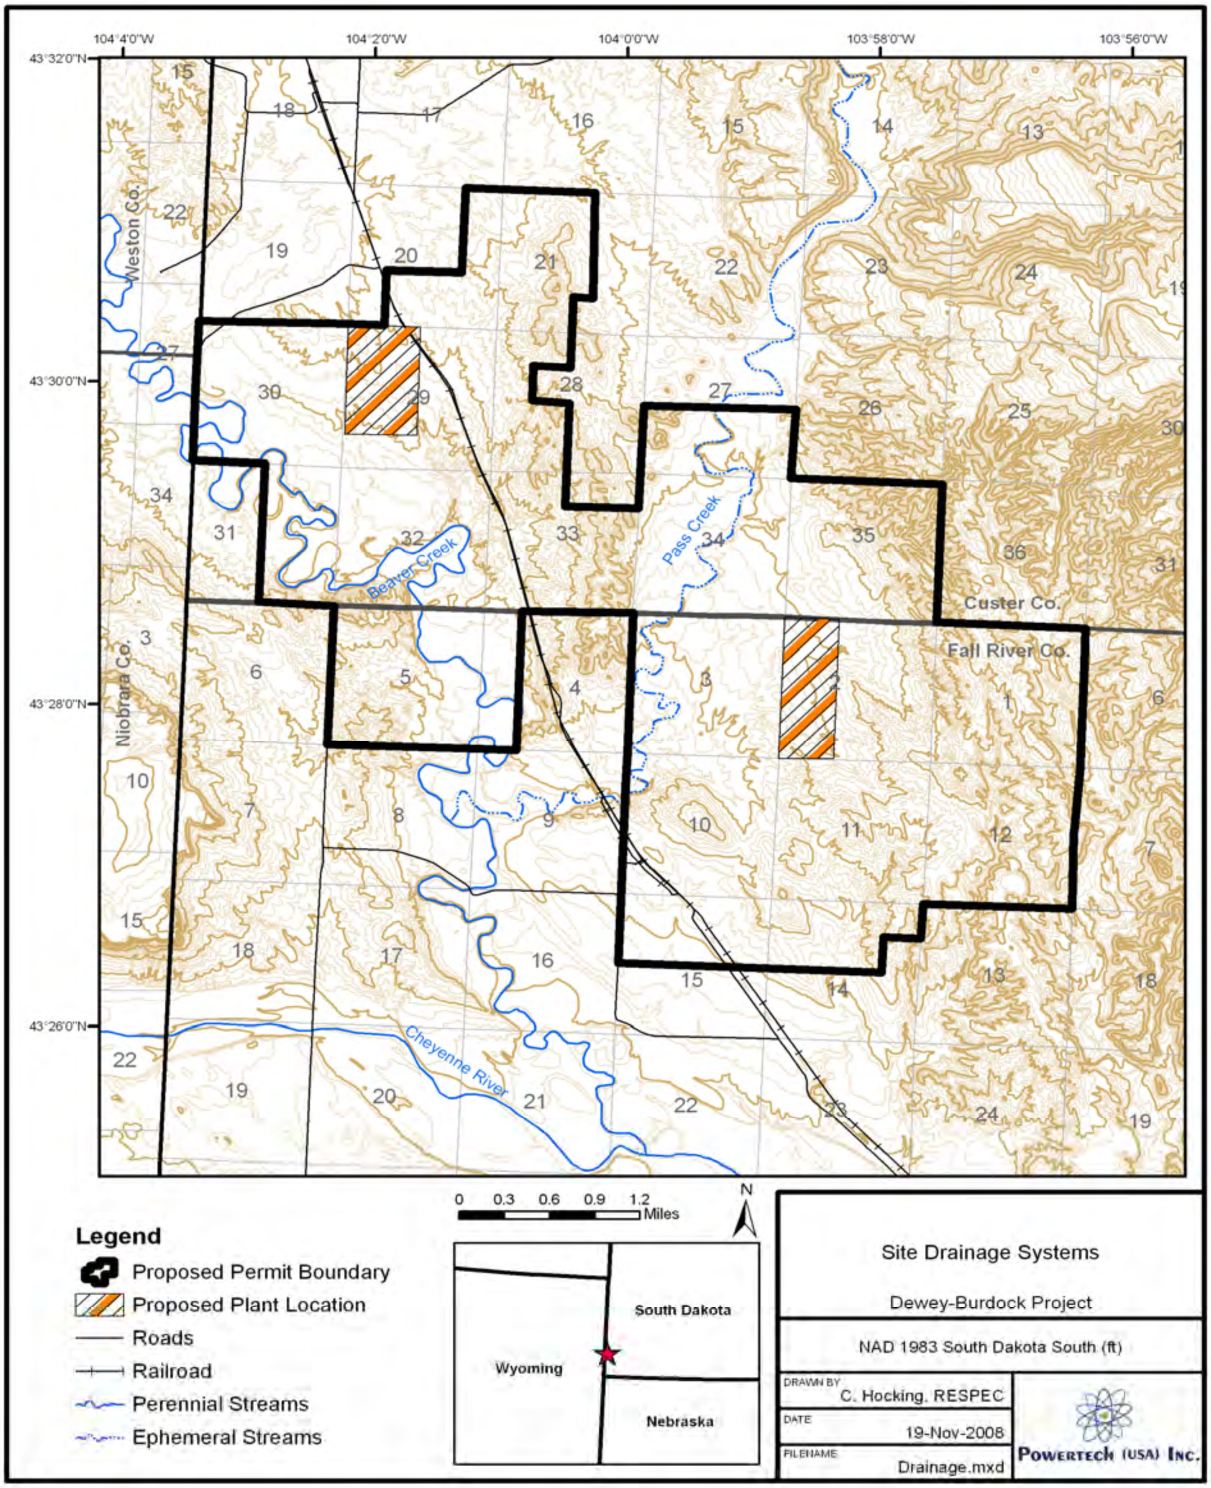

Figure 7.7-1 Site Drainage Systems

7.7.1.2 <u>Site Hydrology</u>

The local hydrology and surface water resources are described for the PAA and for the two main drainage systems that pass through the site (Beaver Creek and Pass Creek) (Figure 5.3-1).

7.7.1.3 Topography

The PAA is characterized by low to moderately sloping brush land with areas of moderately steep ridges. The elevation ranges from approximately 5190 feet to about 3310 feet within the site. The slopes within the site range from 0 percent to 92 percent, with an average slope of nearly 6 percent. Two primary facility zones exist within the PAA. Both the eastern and western facility zones have an average slope of nearly 3 percent.

7.7.1.4 Drainage Basins

The PAA lies primarily within the Beaver Creek Basin and is drained by both Beaver Creek and Pass Creek. The Pass Creek watershed is a sub-basin within the Beaver Creek basin, but the two watersheds were characterized as separate basins. The Beaver Creek system flows through the northwestern section of the PAA from the northwest to the southeast. The Pass Creek system flows south through the central portion of the PAA and joins Beaver Creek southwest of the PAA. Three miles south of this confluence, Beaver Creek converges with the Cheyenne River (Figure 5.3-1) which eventually flows into the Missouri River.

The nearest discharge gage on the Cheyenne River upstream of its confluence with Beaver Creek is USGS gage 06386500 near Spencer, WY. The nearest discharge gage downstream of the confluence of Beaver Creek and the Cheyenne River is USGS gage 06395000 at Edgemont, SD. This gage captures the contribution of flow to the Cheyenne River from Beaver Creek and Pass Creek between Spencer, WY and Edgemont, SD. Figure 7.7-2 shows an annual hydrograph for gage 06386500 from 1948 to 2008, and Figure 7.7-3 shows an annual hydrograph for gage 06395000 from 1903 to 2008. The lines in Figures 7.7-2 and 7.7-3 indicate the upper bound flow values for the 25th, 50th, and 95th flow percentiles for each of the 365 days per year. For example (in Figure 7.7-3), based on all of the January 1st flow values during 1903 to 2008 (106 data points), the flow was less than 1 cfs on 25 percent of those days (26 days), less than 4 cfs on 50 percent of those days (53 days) and less than 30 cfs on 95 percent of those days (101 days). Therefore, the graph indicates how variable the stream flow tends to be at various times during the year (e.g., more variable during a typical July than a typical November).

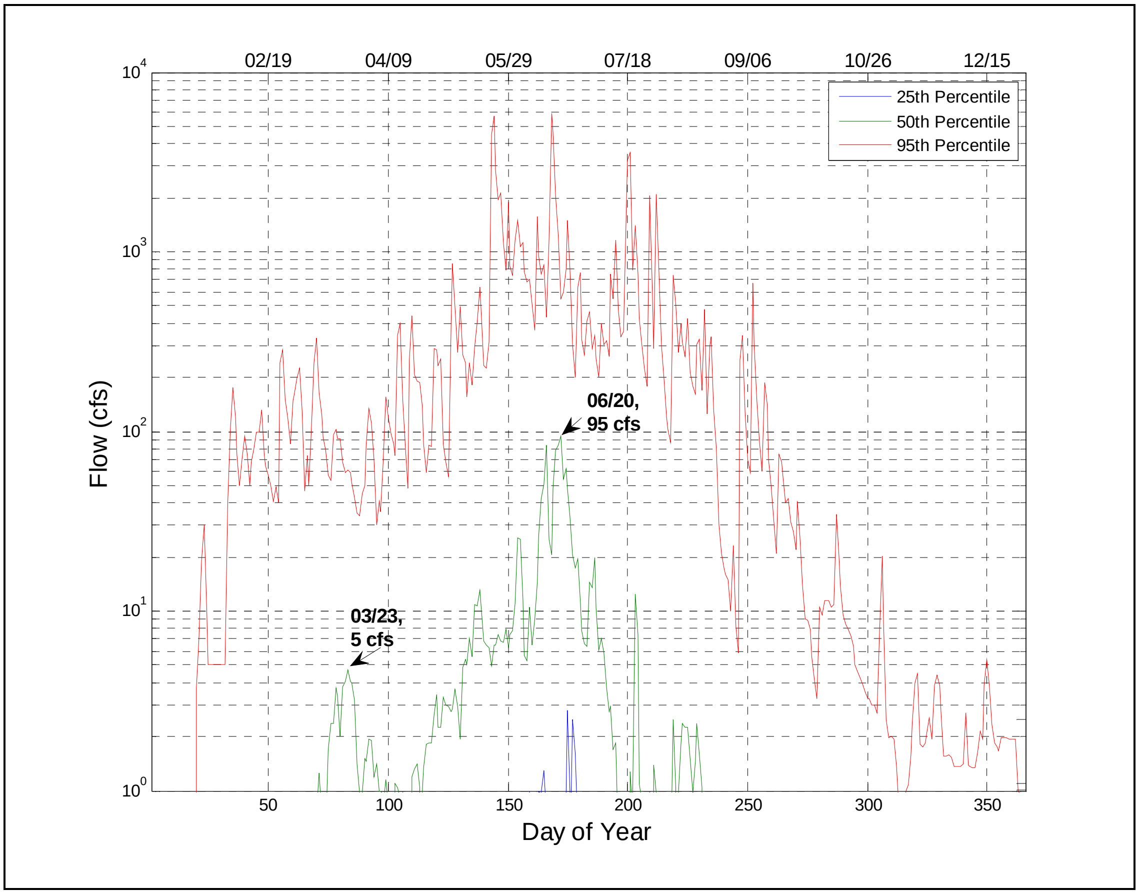

Figure 7.7-2 Annual Hydrograph for USGS Gage 06386500 on the Cheyenne River near Spencer, WY from 1948 to 2008

POWERTECH (USA) INC.

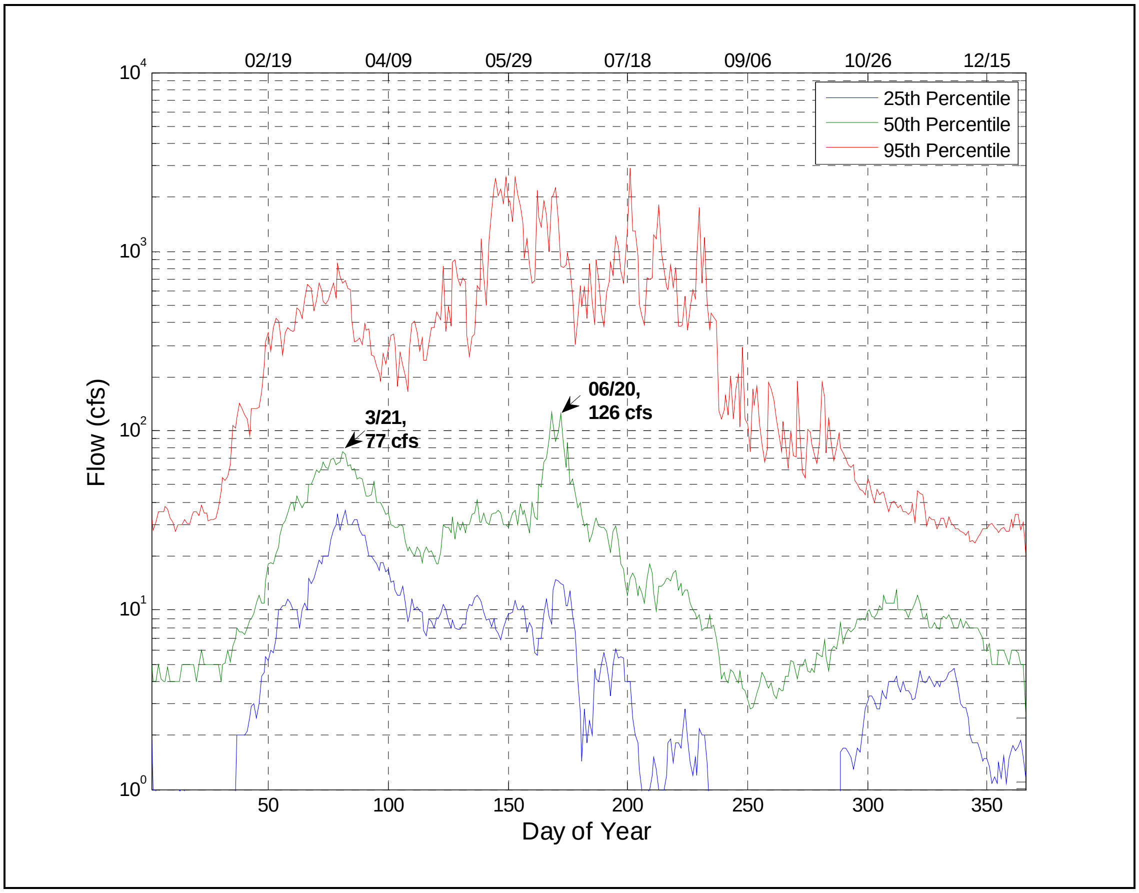

Figure 7.7-3 Annual Hydrograph for USGS Gage 06395000 on the Cheyenne River at Edgemont, SD from 1903 to 2008

7.7.1.4.1 Beaver Creek Basin

The Beaver Creek Basin is 1360 mi^2, excluding the Pass Creek sub-basin. It extends from a few miles northwest of Upton, WY to about eight miles southeast of Dewey, SD and lies within Weston, Niobrara and Crook Counties in Wyoming, and within Pennington, Custer and Fall River Counties in South Dakota. Beaver Creek is a perennial stream with ephemeral tributaries. Discharge data for Beaver Creek is collected at USGS gage 06394000 near Newcastle, WY (Figure 5.3-4). Figure 7.7-4 shows an annual hydrograph with the 25th, 50th and 95th flow percentiles for this gage from 1944 to 1998. Figure 7.7-5 shows monthly average flow data for this gage from 1944 to 1998.

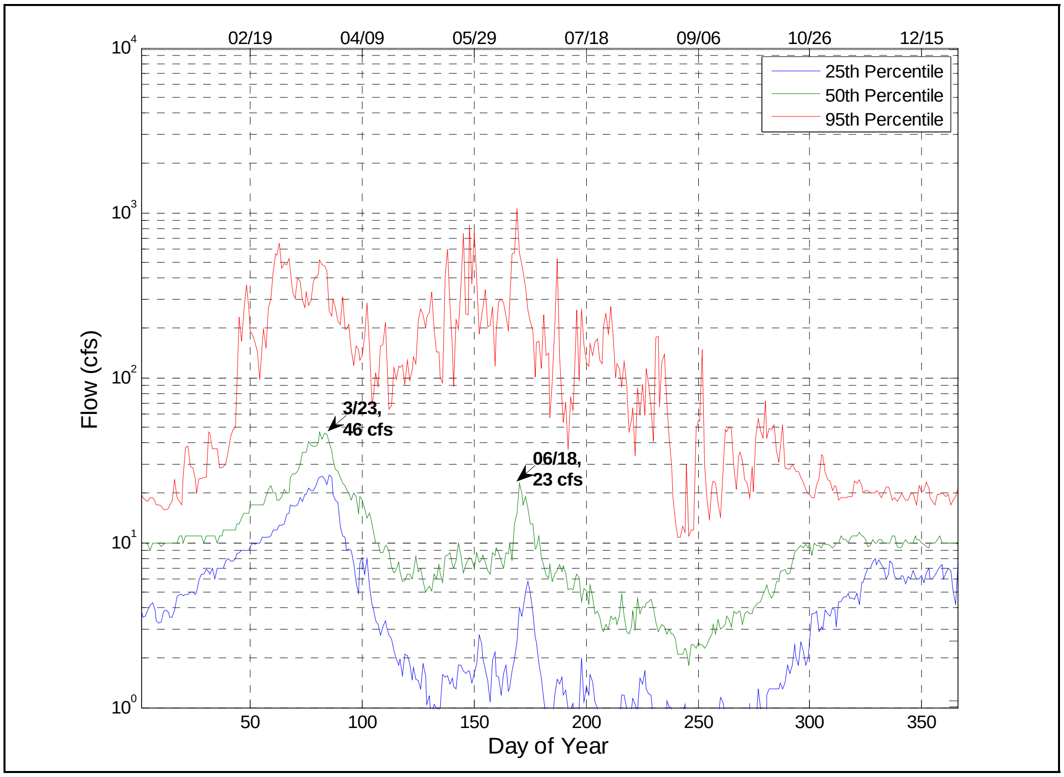

Figure 7.7-4 Annual Hydrograph for USGS Gage 06394000 on Beaver Creek near Newcastle, WY from 1944 to 1998

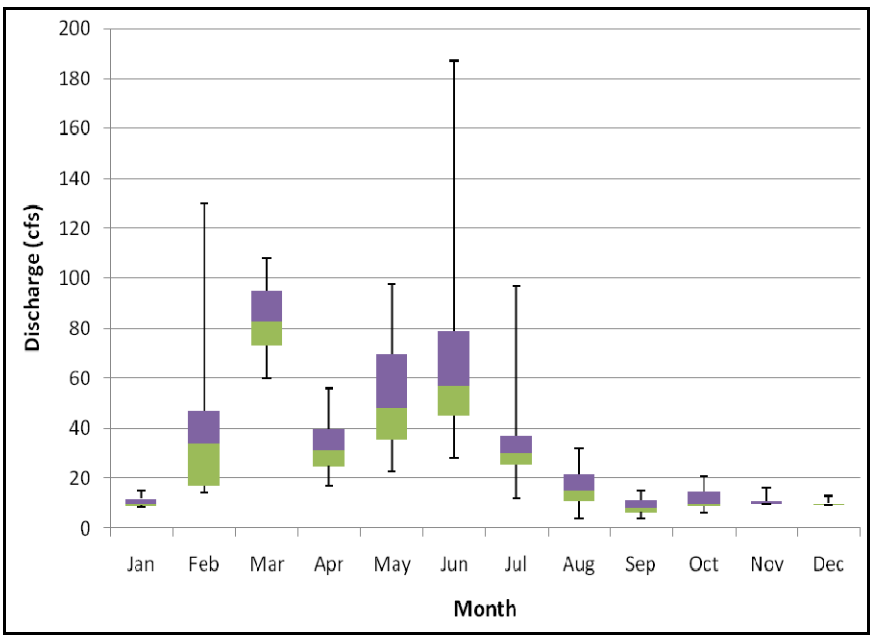

Figure 7.7-5 Monthly Average Flows at USGS Gage 06394000 on Beaver Creek near Newcastle, WY from 1944 to 1998

7.7.1.4.2 Pass Creek Watershed

The Pass Creek watershed, characterized as a subbasin of the larger Beaver Creek Basin, comprises most of the east-southeast portion of the Beaver Creek Basin and is almost fully contained in South Dakota. The Pass Creek watershed is 230 mi^2 and is located in Custer, Fall River, and Pennington Counties in South Dakota and a very small portion of Weston County in Wyoming. Pass Creek is dry except for brief periods of runoff following major storms. There is no permanent stream flow gage stationed along Pass Creek.

7.7.1.4.3 Project Boundary

The northwestern section of the PAA drains to Beaver Creek via an intermittent tributary. The north-central and east-central section of the PAA is drained via Pass Creek and smaller, ephemeral tributaries. The southeast portion of the PAA is also part of the Cheyenne River Basin that drains into the Cheyenne River through East Bennett Canyon. The PAA contains many intermittent streams and drainage channels, particularly in the eastern extent, that are consistently dry throughout the year. Stream flow only occurs in these channels after significant precipitation or snowmelt events and even then may not be of considerable amounts. Three small ephemeral stream channels cut through the primary facility zone in the eastern section of the PAA. Most of the small impoundments that exist within the PAA are dry during most of the year (Exhibit 7.9-1). Many of these existing impoundments are found along ephemeral streams and tributaries, particularly in the eastern section of the PAA.

7.7.1.4.4 Proximity of Surface Water Features to Proposed ISL Facilities

Beaver Creek is the primary surface water resource in the PAA. There will be no ISL operations within 0.4 miles of the Beaver Creek channel, with the exception of two very small areas of known ore bodies that may involve in situ leach well installations and associated piping (Refer to Exhibits 3.1-2).

Pass Creek is a secondary surface water resource in the PAA, although the channel is almost always dry. There will be no in situ leach operations within 0.5 miles of the Pass Creek channel, with the exception of one small orebody that may involve in situ leach well installations and associated piping.

The remaining surface water resources in the PAA are small intermittent stream channels and small ponds which are used by livestock when water exists. With the exception of two ponds in the eastern section of the PAA, just south of the Custer-Fall River County line, no ponds are located in the PAA primary facility zones. Several small, local drainage channels pass through the primary facility zone of the eastern site. The buildings, surface impoundments, and other major facilities constructed in these areas will be located far enough away from these intermittent drainage channels so that no flooding of the facilities will occur, and so that the occasional overland flow hydrographs will not be changed by the presence of these facilities.

7.7.1.5 Surface Water Run Off

7.7.1.5.1 General Approach

The potential for flood or erosion damage in the PAA was evaluated by developing a design flood using statistical methods and a computer model for watershed hydrology in accordance with NUREG-1569. Peak discharge of the design flood was then transformed to a water level using a computer model for stream hydraulics. This approach provides a floodplain map that shows the maximum area inundated by the design flood, as well as detailed information on the depth and velocity of flood water at points of interest in the study area. The 100-year event was used for the design flood, along with a much less likely flood referred to as an upper-bound flow or an extreme flow.

The 100-year event represents an appropriate level of risk for the evaluation of flood potential near the PAA facilities. The extreme flow event was used to demonstrate the additional extent of land that would be inundated between the 100 year event and floods that have an extremely low probability of occurring.

The uncertainty in the analysis and the flood potential at various locations in the PAA are evident when the two scenarios are compared. If a floodplain map shows a small increase in the area of land inundated by the 100-year and the extreme flows, compared to the distance and elevation difference between the edge of the 100-year floodplain and the nearest structure of concern, then the risk analysis is robust and the potential for flood damage to the nearest structure is extremely low. However, if a floodplain map shows a large increase in the area of land inundated between the 100 year and the extreme flows, compared to the distance and elevation difference between the edge of the 100 year floodplain and the nearest structure of concern, then the risk analysis may be too sensitive to the design event selected (i.e., the 100-year flood) and the potential for a flood to damage the nearest structure could be too high. This approach avoids attempts to quantify the 500-year or 1,000-year flood event for example, which involves significant uncertainty because the time period of the observed hydrologic data is too short for such a long return period.

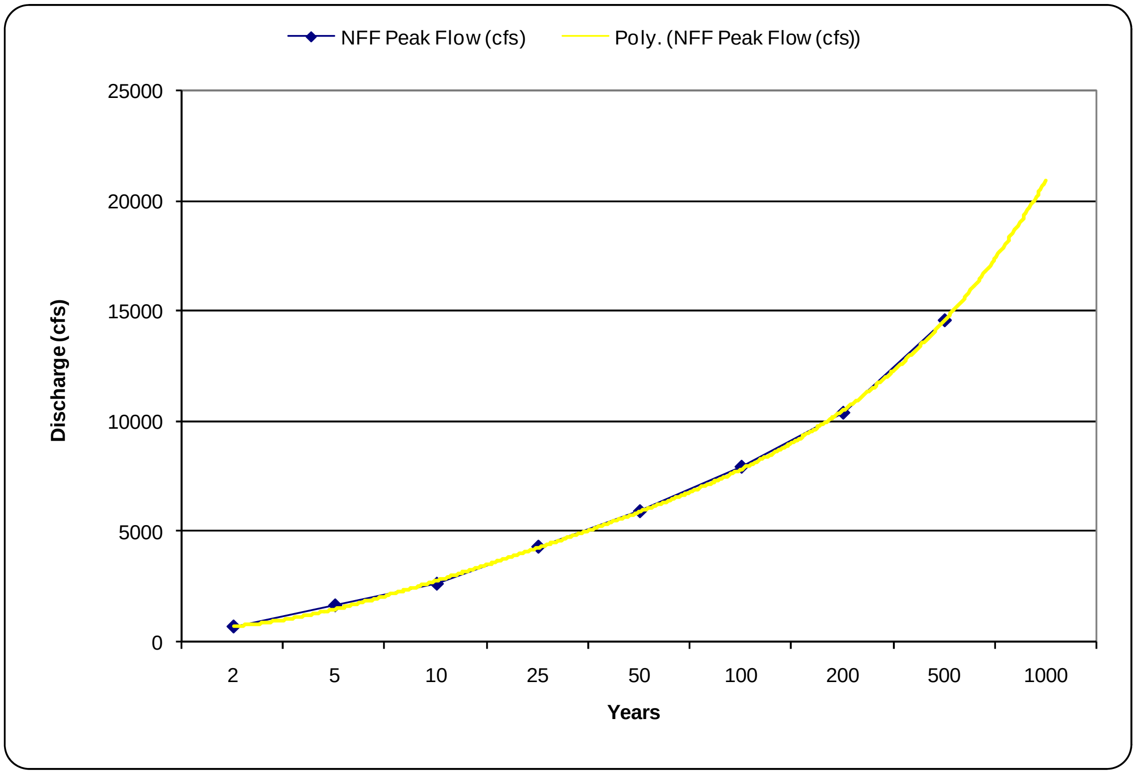
The 100-year flows were developed using hydrologic analyses for Beaver Creek and Pass Creek. These flows are then transformed to maximum water levels using a stream channel hydraulic model. Upper-bound flows, or extreme flows, were developed for each creek and used for comparison with the 100-year event. Floodplain maps showing the proximity of primary facility zones to the maximum level of floodwater were generated for each scenario.

7.7.1.5.2 Hydrologic Analysis – Beaver Creek

USGS gage number 06394000 is located along Beaver Creek near Newcastle, WY (Figure 5.3-1). Statistical methods were used to estimate the design flows. Three software programs were used: National Flood Frequency (NFF) Program 3.2 (Ries and Crouse, 2002), PKFQWin 5.0 (Flynn and others, 2006), and a Matlab Flood Frequency Analysis program (Rao and Hamed, 2000).

The NFF program uses sub-watershed areas, geographical information, and precipitation averages to estimate flood events based on regional regression analyses. The PKFQWin and Matlab programs use the 55 years of historical peak flow at gage 06394000 to estimate flood events. The NFF and PKFQW in methods compute estimated floods ranging from 2- to 500-year frequencies. Beyond that range, a fourth-order polynomial trend-line was used to estimate an extreme condition flood with a relative return period of approximately 500 years to 1500 years.

The sub-watershed areas required by the NFF program were established using ArcHydro 9.2, a GIS watershed delineation tool. The watershed boundaries were in Regions Two (Central Basin and Northern Plains) and Four (Eastern Mountains). Watershed areas for these regions are 971 mi^2 and 387 mi^2, respectively. The analysis for Region Four also required values for mean March precipitation (1.05 inches) – obtained from the National Oceanic and Atmospheric Administration (NOAA) – and latitude of the basin outlet (43.6 degrees north). The discharge results from the NFF program with return periods ranging from 2 to 500 years are given in Figure 7.7-6. The figure also shows the fourth-order polynomial trend-line used to extrapolate the NFF results to an extreme condition flood. The flood estimates from the NFF approach are listed in Table 7.7-1.



Note: Obtained from the NFF program and extrapolated with a 4th order polynomial trend-line to estimate and extreme condition flood.

Figure 7.7-6 Beaver Creek Flood Estimates

Table 7.7-1 Flood Estimate Results for Beaver Creek

Recurrence Interval (years)	Peak Flow (cfs)
2	700
5	1,660
10	2,640
25	4,320
50	5,930
100	7,950
200	10,400
500	14,600
Extreme Condition	22,000

The Matlab program used seven distributions to analyze the historical peak flows. The program ran a test hypothesis on the estimated flood events using the Klomo-Smirnov and Chi-squared procedures. Of the seven distributions, the Klomo-Smirnov method was accepted for the Log Pearson Type III distribution. The flood estimates from the Matlab programs are shown in Table 7.7-2.

Table 7.7-2 Flood estimate results for Beaver Creek

Recurrence Interval (years)	Peak Flow (cfs)
100	6,570
200	7,910
Extreme Condition	11,500

PKFQWin used a Pearson Type III distribution with a weighted and generalized skew, and computed slightly higher results than the NFF program. The PKFQWin results are shown in Table 7.7-3.

Table 7.7-3 PKFQWin Flood Estimate Results for Beaver Creek

Recurrence Interval (years)	Weighted Peak Flow (cfs)	Generalized Peak Flow (cfs)
5	1,840	1,870
10	2,750	2,700
25	4,340	4,070
50	5,940	5,350
100	7,980	6,870
200	10,560	8,680
500	15,030	11,600
Extreme Condition	23,000	17,000

The flood estimates for Beaver Creek are summarized in Table 7.7-4. The final flow values selected for the floodplain analysis of Beaver Creek were 7,990 cfs and 23,000 cfs representing the 100 year and extreme condition floods, respectively. These values were chosen because they represent the most conservative design flow estimates.

Table 7.7-4 Summary Flood Estimate for Beaver Creek

Recurrence Interval (years)	PKFQWin Estimate (cfs)	NFF Estimate (cfs)	MATLAB Estimate (cfs)
100	7,990	7,950	6,570
Extreme Condition	23,000	22,000	11,500

7.7.1.5.3 Hydrologic Analysis – Pass Creek

There are no gage sites along Pass Creek or its tributaries (Hell Canyon, West Hell Canyon, Sourdough Draw, and Tepee Canyon) to provide accurate flow data. To obtain design flow values for the stream channel of Pass Creek within the PAA, a rainfall runoff model was used along with design rainfall to generate stream flows with a range of exceedance probabilities. The 100-year event was used as the primary condition for evaluating the risk of flooding and erosion in the Pass Creek area. An upper bound or extreme condition was represented by 50 percent of an estimated probable maximum flood, for comparison with the 100-year event.

The Hydrologic Modeling System (HEC-HMS) is designed to simulate the precipitation-runoff processes of dendritic watershed systems. The Geospatial Hydrologic Modeling Extension (HEC-GeoHMS) is a software package for use with the ArcView Geographic Information System (GIS). HEC-GeoHMS analyzes digital terrain information and transforms the drainage paths and watershed boundaries into a hydrologic data structure that represents the watershed response to precipitation.

In order to use the HEC-HMS model a high resolution DEM was developed. Contour data from the U.S. Geological Survey 1:24,000 topographic maps were used with ArcGIS to create a grid of elevation data. Plotting stream elevation values against distance downstream indicated that adjacent stream vertices were within two feet of each other, providing good accuracy for this type of analysis.

The HEC-GeoHMS basin model of the Pass Creek watershed was imported into HEC-HMS and the meteorological models and control specifications were created. The 100-year/24-hour storm and the probable maximum precipitation (PMP) were used as the driving precipitation events. Estimates for the 100-year/24-hour storm were obtained from the national depth-duration-frequency maps (US Department of Commerce) (Table 7.7-5). The PMP estimate was obtained from HMR-51 depth-area-duration maps (Schreiner and Riedel, 1978) (Table 7.7-6). The comprehensive approach of HMR-52 (Hansen, et al, 1982) for developing a probable maximum flood (PMF) was not used. Instead, a simplified approach was developed using the PMP estimate as with conventional rainfall runoff modeling techniques. The resulting flood is therefore referred to as an estimated probable maximum flood (estimated PMF) and represents an appropriate extreme event for comparison with the 100-year event. Figure 7.7-7 shows a graphical representation of the PMP estimates for the Pass Creek watershed's geographical location. The depths and durations for the PMP on the Pass Creek watershed are shown in Table 7.7-7.

Table 7.7-5 Depth-Duration Data for the 100-Year Storm Event

100-year Storm	
Duration	Depth (in)
5 min	0.79
15 min	1.58
60 min	2.50
2 hour	3.00
3 hour	3.20
6 hour	3.60

Two control specifications (time periods used to capture the response of a watershed from a precipitation event) were created for the HEC-HMS model of the Pass Creek watershed. The first used a 4-day duration with 15-minute time intervals for the 100-year/24-hour storm, and the second used a seven day duration with six hour time intervals for the PMP.

The loss and transform methods used in the HEC-HMS model of the Pass Creek watershed were the SCS Curve Number and SCS Unit Hydrograph, respectively. Both of these methods rely heavily on a curve number (CN) which is a characterization of soil type, land use and cover, and antecedent soil moisture. These parameters were estimated based on a field inspection of the Pass Creek watershed on May 21, 2008, on the Soil Survey Geographic (SSURGO) Database and on county land use data. Parameters for the loss and transform methods include CN, storage (S), initial abstraction (I_a) and lag time (t_l).

Curve numbers were assigned to different sub-watershed sectors, and area-weighted CNs were developed for the entire Pass Creek watershed for standard conditions (CN = 57) and for conservative conditions (CN = 63). An impervious area of five percent was also estimated based on field investigations. The CN of 63 was used in the model, providing a conservative approach because the higher CN would result in a larger percentage of rainfall becoming runoff.

The parameter values used in the loss and transform methods of the model were a CN of 63, S equal to 5.87 inches, I_a of 1.18 inches and t_l equal to about 1,231 minutes. The values of S, I_a and t_l are based on the CN in that their value is heavily influenced by the value of the CN.

The output results for both precipitation events in the HEC-HMS model of the Pass Creek watershed are shown in Table 7.7-8. Due to the extreme condition represented by the PMP meteorological model, the estimated PMF was reduced by a factor of 0.5. This resulted in a 50 percent estimated PMF peak discharge of approximately 32,800 cfs.

Table 7.7-8 Discharge Results for the Single Basin Model of the Pass Creek Watershed

Event	Peak Discharge (cfs)
100yr	5620
Estimated PMF	65600
50% Estimated PMF	32800

The final flow values used for input to the HEC-RAS model of Pass Creek were 5,620 cfs and 32,800 cfs representing the 100-year and extreme condition floods, respectively. These flow values resulted from a conservative approach to parameter estimation and modeling. The model used the higher CN and a single basin versus many smaller sub-basins with routing. This combination results in a larger instantaneous peak flow entering the stream channel of Pass Creek within the PAA. The extreme condition flood is only included to illustrate the extent of the flood plain during an extremely low probability flood event, and its relation to the primary facility zones. The estimated PMF and 50 percent of the estimated PMF are extremely rare events and represent conditions much more severe than the design scenarios discussed in NRC 1569 for in situ leach extraction operations.

7.7.1.5.4 Floodplain Analysis – Beaver Creek and Pass Creek

The stream channels of both Beaver Creek and Pass Creek within the PAA were each modeled using the Hydraulic Engineering Center River Analysis System (HEC-RAS) and the Geospatial River Analysis Extension (HEC-GeoRAS) to determine the spatial representation of the floodplains resulting from the simulated 100-year flood and extreme condition flood.

HEC-RAS software simulates one-dimensional steady and unsteady river hydraulics. The system can handle a full network of channels, a dendritic system, or a single river reach. HEC-RAS is capable of modeling subcritical, supercritical, and mixed flow regime water surface profiles.

The Geospatial River Analysis Extension (HEC-GeoRAS) is a set of ArcGIS tools specifically designed to process geospatial data for use with HEC-RAS. The extension enables efficient creation of a HEC-RAS import file containing geometric data from an existing digital terrain model (DTM) and a National Hydrography Dataset (NHD) flowlines shapefile. Results exported from HEC-RAS may also be processed using HEC-GeoRAS to create layers and floodplain maps in ArcMap.

The HEC-RAS model is based largely on a framework of geometric data which provides a representation of the physical characteristics of a river. For both Beaver Creek and Pass Creek, HEC-GeoRAS was used to extract the necessary elevation and geometric data for the channel and floodplain from the same DEM developed for the HEC-HMS analysis. The process for each creek was nearly the same except for the extra details required to characterize the two bridges spanning Pass Creek just downstream of the southern portion of the PAA. The road and railroad bridges had the potential to cause backwater effects and were therefore included in the Pass Creek analysis though they were outside of the PAA. The geometry and elevation data of both bridges were measured on April 12, 2008.

The geometry files generated with HEC-GeoRAS in ArcGIS were imported into HEC-RAS and inspected for completeness. For each creek, ineffective flow areas were added where necessary and Manning's n values were assigned for the left overbank, the channel, and the right overbank. Conservative Manning's n values were established during a field inspection of the Beaver Creek and Pass Creek channels within the PAA on May 21, 2008 (Table 7.7-9). Figures 7.7-8 and 7.7-9 are photos of the Beaver Creek and Pass Creek stream channels along with their floodplains taken during the site inspection.

Data entry for the bridges in the downstream section of Pass Creek was manually performed. Low flow calculation methods for the road bridge and railroad bridge included the energy and momentum methods. Pressure and weir methods were used for high flow computation of the road bridge while energy only was used for the railroad bridge.

Table 7.7-9 Manning's n Values for the Beaver Creek and Pass Creek Channels

Creek	Manning's n Value		
	Left Overbank	Channel	Right Overbank
Beaver, upstream	0.060	0.045	0.060
Beaver, downstream	0.053	0.040	0.053
Pass	0.065	0.050	0.065

Note: based on field observations

Two steady flow profiles were created for each creek: the 100-year flood and the extreme condition flood (a 500-year – 1500-year flood for Beaver Creek and 50 percent of the estimated PMF for Pass Creek). Flow estimates generated from PKFQWin and HEC-HMS were entered for each profile of Beaver Creek and Pass Creek, respectively. Downstream boundary conditions used normal depth with updated slopes of the energy grade lines.

Figure 7.7-8 The Beaver Creek Stream Channel and Floodplain

Note: location is in the southwest extent of the PAA, just east of the confluence with Beaver Creek. Photo taken from the road bridge along South Dewey Road, looking east.

Figure 7.7-9 The Pass Creek Stream Channel and Floodplain

7.7.1.5.5 <u>Floodplain Analysis – Results</u>

The HEC-RAS analysis involved an iterative procedure of creating a model run – based on an input geometry file and a steady flow profile(s) – and reviewing output summary tables and warning and error messages. From this process, the geometry file was revised multiple times by adding cross sections to adequately balance the energy losses throughout the model for each creek.

The final model results for the spatial representation of the 100-year floodplains for Beaver Creek and Pass Creek within the PAA are shown in Figures 7.7-10 and 7.7-11, respectively. The figures indicate the relationship of the maximum extent of the 100-year floodplain to the locations of the primary facility zones and the known ore bodies. The horizontal and vertical distances separating the primary facility zones and known ore bodies from the 100-year floodplain for each creek are shown in Table 7.7-10.

Table 7.7-10 Proximity Data for the 100 Year Floods of Beaver Creek and Pass Creek

Creek	Concern	Horizontal Distance (ft)	Vertical Distance (ft)
Beaver			
	Facilities	2,190	32
	Ore Bodies	170	15
Pass			
	Facilities	2,180	30
	Ore Bodies	340	10

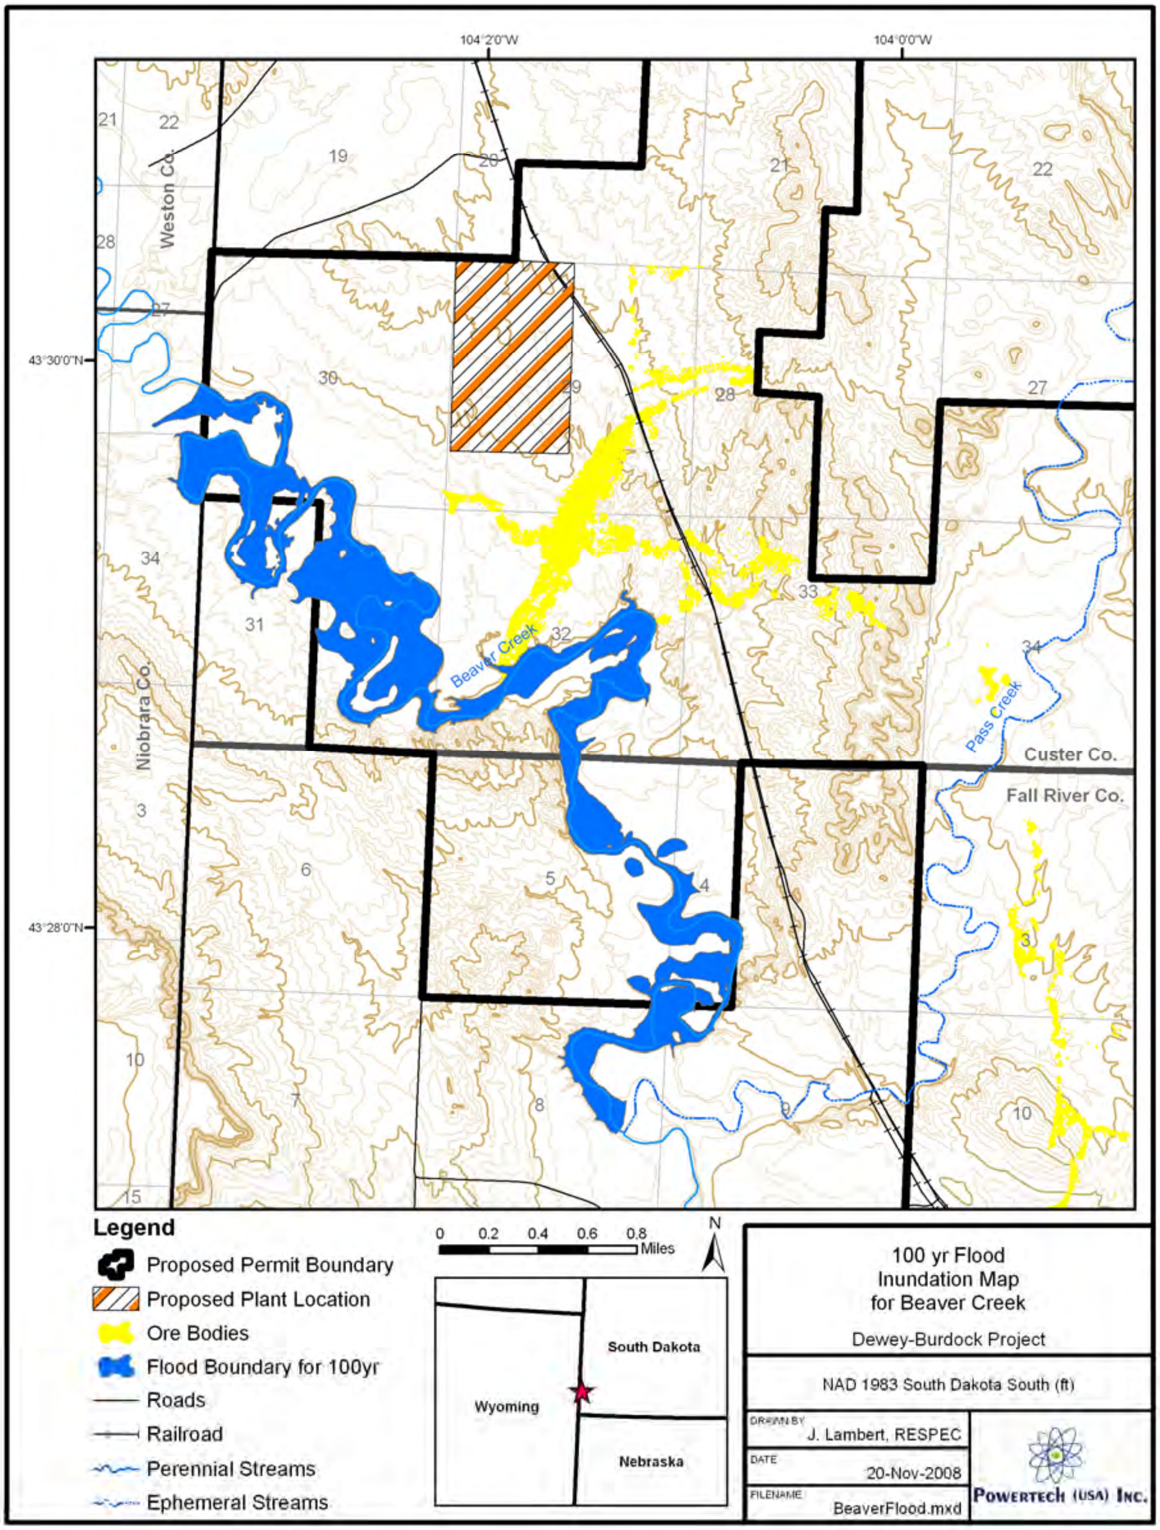

Figure 7.7-10 100 Year Inundation Map for Beaver Creek

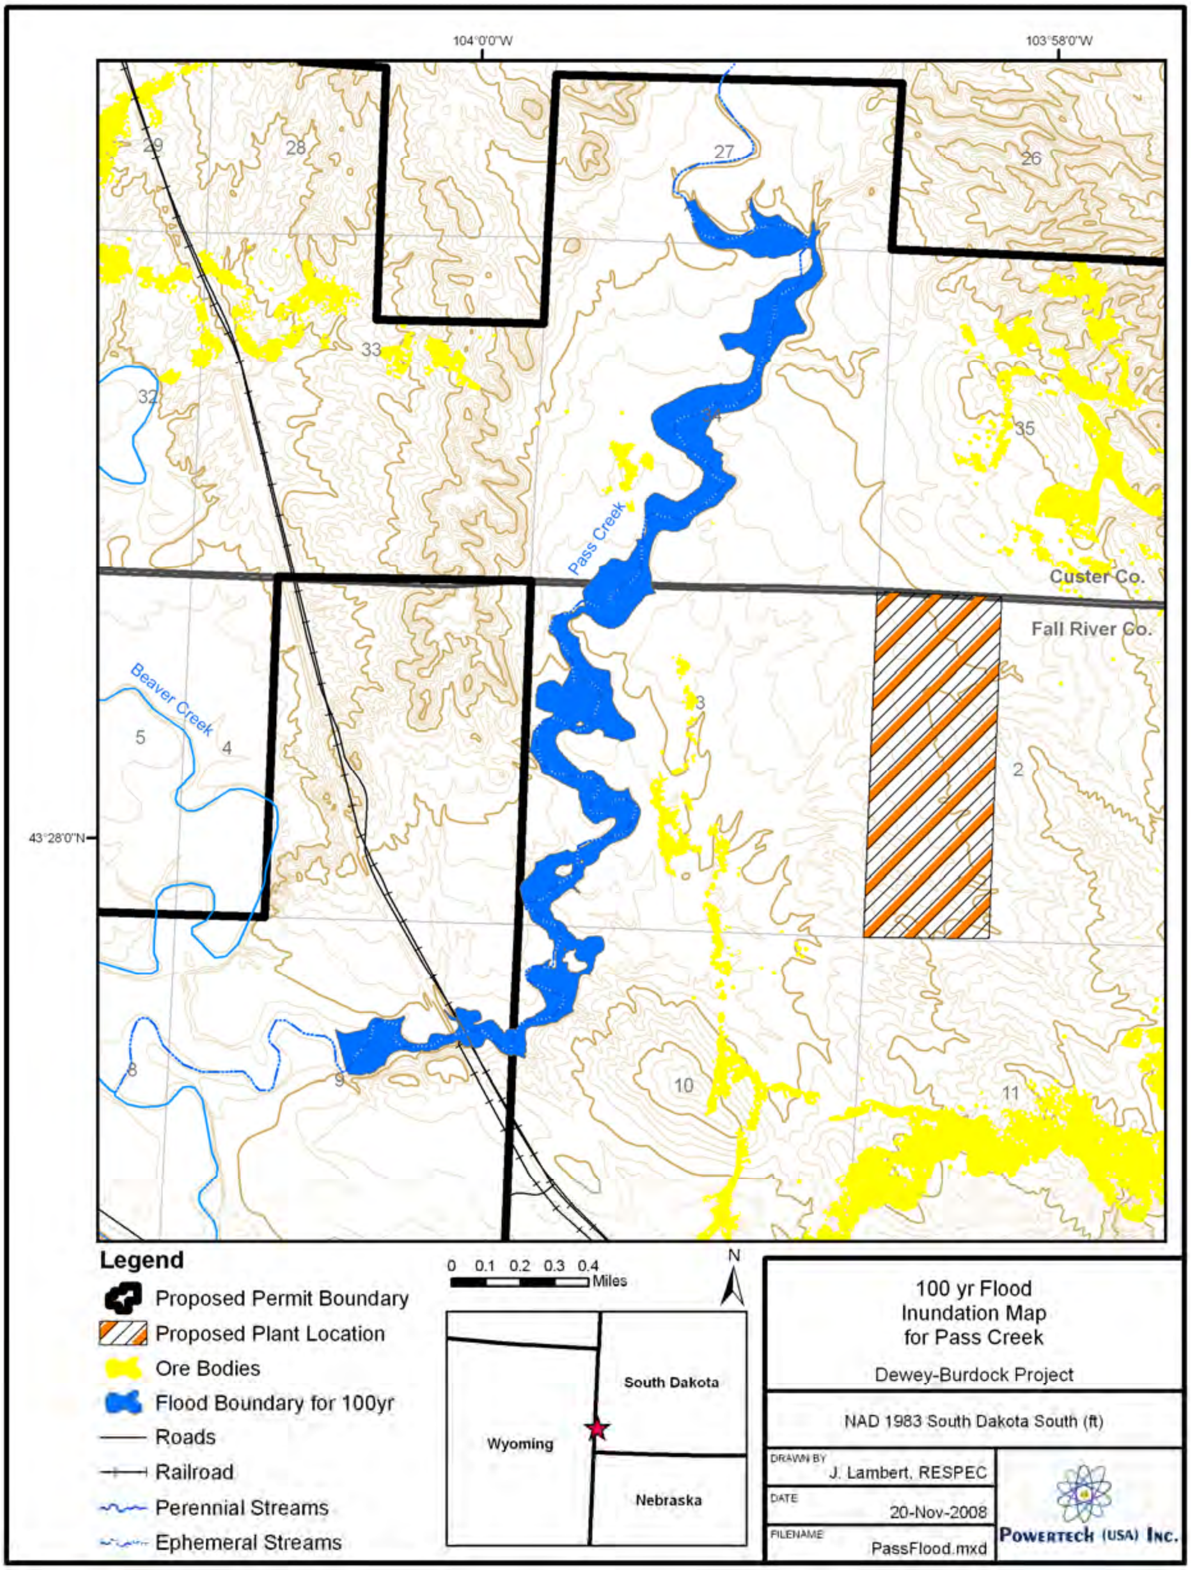

Figure 7.7-11 100 Year Inundation Map for Pass Creek

The final model results for the spatial representation of the extreme condition floodplains for Beaver Creek and Pass Creek within the PAA are shown in Figures 7.7-12 and 7.7-13, respectively. The figures indicate the relationship of the maximum extent of the extreme condition floodplain to the locations of the primary facility zones and the known ore bodies. The horizontal and vertical distances separating the primary facility zones and known ore bodies from the extreme condition floodplain for each creek are shown in Table 7.7-11. The sole purpose of including the extreme condition flood in the analysis for flood and erosion potential is to illustrate that there is very little additional land area inundated by the extreme condition floods than by the 100-year floods. The risk of flood or erosion damage to the PAA facilities from Beaver and Pass Creeks is extremely low.

The inundation maps of Pass Creek indicate that known ore bodies in the upstream section of the creek would become inundated. It is estimated that the water depths would be 15 feet for the 100-year flood and approximately 25 feet for the extreme condition flood.

Table 7.7-11 Proximity Data for the Extreme Condition Floods of Beaver Creek and Pass Creek

Creek	Concern	Horizontal Distance (ft)	Vertical Distance (ft)

7.7.1.5.6 Flooding and Erosion in Local Drainages

There are no significant local drainage systems that could impact the primary facility zone in the western area of the project site (e.g., buildings housing critical processes, or surface impoundments). There are several small, local drainage systems that could occasionally produce flow in small channels that pass through the primary facility zone in the eastern section of the PAA. The largest system drains a 0.5 square mile catchment (measured upstream of the eastern border of the proposed eastern primary facility zone, 0.2 miles south of the Custer-Fall River County line). The average slope of this watershed is 3 percent, and the channel slope just upstream of the primary facility zone is 2 percent. The maximum length of the drainage path from the primary facility zone upstream to the drainage divide is one mile. Several other drainage systems that could occasionally carry flow through the proposed site are similar to this system, but have smaller drainage areas.

These small catchments could occasionally produce floods with significant flow but relatively short duration. Velocities of concentrated flow created by the existing rainfall runoff processes are high enough to erode these channels. The project operations can be protected from impacts due to erosion and flooding related to these local systems by applying standard engineering methods associated with urban storm water management. Specific structures and facilities should be located out of the drainage paths of these catchments. Construction should not occur in areas where the structure could alter the existing runoff hydrograph or reduce the existing stability of the drainage channels. On-site runoff due to roofs, parking lots and other impervious areas constructed for the project should be managed so that it is released to the natural channel systems without increasing the erosion that would naturally occur due to runoff from the watersheds upstream of the project facilities.

7.7.1.5.7 7.7.1.5.7 Assessment of Levels of Surface Water Bodies

The purpose of the assessment is to characterize the typical seasonal ranges and averages as well as the historical extremes of levels of surface water bodies within the PAA. Surface water bodies within the PAA are surface impoundments such as ponds and old mine pits. Historical stage data for these surface water bodies is unavailable, and the stage data that has been collected is very limited. The available data for this assessment was collected at 16 sites from October 2, 2007 to July 18, 2008. A summary of this data is shown in Table 7.7-12 which was populated according to site location (Feature ID). Stage data at three of the 16 sites was collected only once while every other site had at least two records with one site having five records. Two of the 13 sites with at least two records had data recorded within three months of each record which would not capture the potential seasonal range of the water level for those two sites. The largest positive and negative changes in water levels over the period of collection were 2.43 feet and -0.48 feet, respectively. The smallest change overall was 0.04 feet. The largest rate of change in water level for each site over its period of collection was 0.011 feet per day or about 0.13 inches per day. The surface water bodies with the largest change in water level are located near the Darrow Mine Pits approximately two miles northeast of Burdock (Feature IDs 10032, 10033 and 10052). Another surface water body is located approximately two miles south of the Darrow Mine which represents the smallest change in water level of any of the surface water bodies (Feature ID 10040). These water level changes were recorded at sites with at least two records and a minimum time span of 206 days which represents the most sufficient data available to characterize the seasonal ranges for water levels of the surface water bodies within the PAA. Further discussion about the interaction between ground water and surface water bodies is provided in the ground water report.

Table 7.7-12 Summary of Water Level Data Collected at Surface Water Bodies

Feature ID	Data Records	Time Interval of Greatest Stage Change (days)	Stage Change (ft)	Stage Change Rate (ft/day)

7.8 Regional Groundwater Hydrology

Four major aquifers are utilized as groundwater resources in the Black Hills. These main aquifers are the Inyan Kara, Minnelusa, Madison, and Deadwood. The groundwater hydrology is influenced by distribution and variation in recharge, leakage between overlying and underlying hydrogeologic units, lateral flow within the aquifers, and discharge to pumping wells, artesian wells, and springs.

Regionally, the general direction of groundwater flow is downdip or radially away from the central part of the Black Hills where the aquifers are recharged via infiltration from local rainfall. The aquifers transition from unconfined at the outcrop areas to confined away from the central highlands. At some distance away from the highlands the groundwater often is under sufficient pressures for artesian conditions and flowing artesian wells to exist.

Refer back to Figure 5.2-3, which provides an overview of the hydrologic setting and general hydrogeologic flow within the Black Hills.

7.8.1 Regional Hydrostratigraphic Units

This section summarizes the aquifers in the Black Hills, including general characteristics and hydraulic properties. Hydrologic units of interest within the Black Hills area are shown on the stratigraphic column in Figure 7.1-2. Table 7.8-1 (from Driscoll et al., 2002) summarizes hydraulic properties of major aquifers determined in previous investigations.

7.8.1.1 Inyan Kara Aquifer

On the prairie away from the central Black Hills, the Inyan Kara is typically the first significant aquifer encountered. The Inyan Kara aquifer is comprised of two sub-aquifers, the Lakota and the Fall River, which are separated by the Fuson shale confining unit. Regionally, the Inyan Kara ranges from 250 to 500 feet. The Inyan Kara is a very heterogeneous formation, which results in the two (2) aquifers exhibiting a large variation in local characteristics. Regionally, the Inyan Kara exhibits a large effective porosity (0.17) and the aquifer can yield considerable water from storage (Driscoll et al., 2002). Within the Black Hills, transmissivity of the Inyan Kara ranges from 1 to 6,000 ft^2/day. This high variability is an indication of the complex heterogeneity of the Inyan Kara formation. The Inyan Kara is confined below by the Morrison Formation (50-100 ft thick) and above by Cretaceous Graneros Group shale.

7.8.1.2 Minnelusa Aquifer

The Minnelusa Formation consists of interbedded siltstone, sandstone, anhydrite, and limestone (SDSM&T, 1963). The Minnelusa aquifer occurs primarily in saturated sandstone and anhydrite beds within the upper part of the formation (Williamson and Carter, 2001). Within the Black Hills, the Minnelusa ranges in thickness from 375 to 1,175 feet (Driscoll et al., 2002). The porosity is dominantly primary porosity within the sandstone beds, although secondary porosity is present in association with fractures and dissolution features (Williamson and Carter, 2001). Various studies have found the transmissivity of the Minnelusa to range from 1 to 12,000 ft^2/day (Table 7.8-1). The Minnelusa aquifer is confined above by the Opeche Shale and below by lower permeability layers at the base of the Minnelusa formation.

7.8.1.3 Madison Aquifer

Within the Black Hills, the Madison Limestone, also known as the Pahasapa Limestone, could be considered the most important aquifer because it is the source of municipal water in numerous communities including Rapid City and Edgemont. The hydraulic characteristics of the Madison Limestone aquifer have been studied for several decades in the region and Table 7.8-1 summarizes the regional findings. The Madison aquifer is mainly a dolomite unit characterized by extensive secondary porosity resulting from fractures and associated karstic features (Williamson and Carter, 2001). The thickness of the Madison ranges from 200 feet in the southern Black Hills to 1,000 feet regionally. In the Rapid City area, Greene (1993) found the transmissivity to vary widely between 1,300 and 56,000 ft^2/day. The aquifer varies from unconfined at its outcrop areas to confined, where reported storativity values range from 10^{-3} to 10^{-6} (Table 7.8-1). Regionally a paleosol and low permeability layers within the overlying Minnelusa Formation act to confine the Madison. Locally, these confining layers may be absent or their hydraulic characteristics are higher such that intercommunication between the Madison and Minnelusa occurs. The Madison may be in connection with the underlying Deadwood aquifer when the Whitewood and Winnipeg confining units are absent.

7.8.1.4 Deadwood Aquifer

Overlying the Precambrian, the Cambrian Deadwood Formation consists of basal conglomerates, sandstone, limestone, and mudstone. The thickness of the Deadwood is between zero (0) and 500 feet (Driscoll et al., 2002). Rahn (1985) estimated the effective porosity of the aquifer to be 0.05. In the northern Black Hills the effective porosity is presumably lower, in areas where the formation has undergone extensive hydrothermal alteration. The transmissivity of the Deadwood within the region is 250 to 1,000 ft^2/day (Table 7.8-1) (Downey, 1984). Regionally, "the Precambrian rocks act as a lower confining unit to the Deadwood aquifer," although local connection can exist (Williamson and Carter, 2001). The Deadwood aquifer is in contact with the overlying Madison aquifer except where the Whitewood and Winnipeg formations are present and act as semiconfining units (Strobel et al., 1999).

7.8.1.5 Minor Aquifers

In addition to the major aquifers, minor aquifers around the Black Hills include the Minnekahta Limestone, Sundance/Unkpapa, Newcastle Sandstone, and alluvium. Where present and saturated, these units may yield small amounts of water. Locally, beds within the confining units may also contain aquifers (Driscoll et al., 2002). Typically, these minor aquifers are not heavily utilized because of more reliable sources in adjacent aquifers.

7.8.1.6 Regional Hydraulic Connection of Aquifers

Because of the geologic variability across the Black Hills, several mechanisms can serve to create hydraulic connection between aquifers. Most interconnection appears to be associated with the thinning or absence of confining units between aquifers, which has been documented in local and regional geologic studies (Miller, 2005). Analyses of regional aquifer tests conducted around the Black Hills provide direct evidence of aquifer interconnection or separation. A few examples are mentioned below.

- Recent pumping tests within the Deadwood aquifer near Jewel Cave indicate that vertical leakage through a confining layer is occurring in that area (Valder, 2006).
- In Rapid City, Rahn (1989) points to different artesian pressures reported in Sioux Park wells, installed into different hydrogeologic units, as evidence that the units are hydraulically separated.

- Studies by Long and Putnam (2002) of paired Madison and Minnelusa wells at the City Quarry site indicate hydraulic connection between these units. The variation in yields between areas indicates that locally the interlaying layers may not provide hydraulic separation between the two units. Both well tests and outcrop observations show the variability of hydraulic connection between the Deadwood, Madison, and Minnelusa aquifers.
- Various sources have also suggested that breccia pipes serve as a path between aquifers. The majority of these features are believed to originate within the Minnelusa Formation and extend upward as high as the Inyan Kara (Gott et al., 1974). These breccia pipes are the result of dissolution of significant thicknesses of anhydrite from the upper Minnelusa and subsequent collapse. The greatest concentration of these breccia pipes has been noted within a few miles of the outcrop, although groups of pipes can be concentrated along joints and may extend as "high in the stratigraphic section as the Lakota Formation" (Braddock, 1963). Gott, Wolcott, and Bowles (1974) believed that these breccia pipes allowed large quantities of water to migrate upwards from the Minnelusa into the Inyan Kara.

7.8.1.7 Regional Potentiometric Surfaces

As part of the Black Hills Hydrology Study, the USGS developed 1:100,000-scale potentiometric maps for five aquifers including the Inyan Kara, Minnekahta, Minnelusa, Madison, and Deadwood (Strobel et al, 2000). The purpose of these maps is to show the potentiometric surface of the aquifers and to serve as a tool for evaluating groundwater flow directions and hydraulic gradients in the Black Hills area. The potentiometric maps were created by contouring elevations of water levels in wells completed in their respective aquifers. Structural features such as folds and faults were also considered in the contouring of the potentiometric surfaces. In areas where the potentiometric contours have been inferred (dashed), deviations between the map and actual water levels may occur. The following conclusions can be drawn from analysis of the figures:

- Regional flow within the different units is consistent for all units. Flow is radially outward from the central highlands toward the plains.
- Near the outcrop, the aquifers are unconfined. With distance, the aquifers are confined and have water levels above the top of the formation, and locally above the land surface.

7.8.1.8 Regional Groundwater Recharge

Aquifers in the Black Hills are recharged by infiltrating precipitation, streamflow losses, and minor seepage from other aquifers. The relative contribution of each of these recharge components is variable in the Black Hills. For instance, recharge is dominated by precipitation on the western limestone plateau, while streamflow dominates in parts of the southern hills (Carter et al., 2000).

The Black Hills are relatively arid with rainfall ranging from 12 to 28 inches per year in the area. Most precipitation can be accounted for as surface runoff or evapotranspiration. Regionally, the percentage of precipitation that recharges the aquifers varies from 30 percent in the northwestern Black Hills to approximately 2 percent in the drier southwestern Black Hills.

Streamflow losses can contribute to aquifer recharge if connection between the stream and underlying aquifer exists. Generally, surface water recharge to groundwater is limited to relatively shallow alluvial aquifers in relatively close proximity to the streams. The exception to this rule occurs in areas where karstic features provide preferential pathways for recharge into the subsurface.

Other sources of recharge to individual units can occur from leakage between units. Regionally, water elevations increase with depth, which provides an upward potential for ground-water flow. This limits the potential for downward recharge. Locally these flow head relationships can be reversed due to pumping of wells, thus creating localized zones where the potential for downward leakage exists.

7.8.1.9 Regional Groundwater and Surface Water Interactions

Throughout the Black Hills there are numerous springs in both the Madison and Minnelusa formations. These springs provide the headwaters for many streams in the western hills (Long and Putnam, 2002). Where these streams cross aquifer outcrops along the eastern Black Hills they lose flow into the subsurface through sinkholes and re-emerge downstream in springs and wells (Rahn, 1971 and Long and Putnam, 2002).

In alluvial aquifers, flow is often exchanged between subsurface and surface water. Many of the streams in the Black Hills are losing streams from which stream water infiltrates into the alluvial aquifers. Streams also can be gaining streams, in which they have increased discharge due to inflow from an alluvial aquifer.

The maximum amount of streamflow loss that occurs is known as the loss threshold. When streamflows are less than the loss threshold, then the discharge is the maximum that can be absorbed as recharge. If streamflow is greater than (or equal to) the loss threshold, then recharge equals the loss threshold and the stream will flow over the entire outcrop area.

Hortness and Driscoll (1998) conducted a study of streamflow loses across the Black Hills. Several factors that have been theorized to affect loss rates include streamflow rate, duration of flow across a loss zone, or deposition of large amounts of sediment. These observations are consistent with factors known to influence recharge into the surface: volume of water available, the time period during which recharge can occur, and connectivity with the subsurface as represented by thickness of overlying sediments. Hortness and Driscoll (1998) found no evidence that loss thresholds were affected by upstream flow rates.

7.9 Site Groundwater Hydrology

The site hydrostratigraphic units are consistent with the regional units discussed above. The hydrostratigraphy and surficial geology at the site are shown in Figure 7.1-2, and Figure7.2-1, respectively. Analyses of groundwater quality data for the units are provided in Section 7.14.

7.9.1 Spearfish Formation Confining Unit

In general, the Spearfish Formation is characterized by a thick sequence (250 to 450 feet) of red shale and siltstone. Based on the few exploration holes that have penetrated the entire thickness of the formation in the PAA, the Spearfish is an average of 320 feet thick. This thick sequence of shale serves as a hydrologic barrier or confining unit preventing nearly all vertical flow between the Paleozoic aquifers and the Jurassic/Cretaceous aquifers.

7.9.2 Sundance and Unkpapa Aquifers

Overlying the Spearfish formation, the Sundance and Unkpapa aquifers are considered aquifers of minor importance within the Black Hills. These aquifers are a source of water within the PAA. The Sundance Formation is composed primarily of shale and sandstone with an average thickness of 280 feet thick near the project site. Where present, the Unkpapa is 50 to 80 feet of well sorted, fine-grained, eolian sandstone. For the purpose of this study, the Sundance and Unkpapa aquifers are considered equivalent as there is no intervening confining unit separating the two.

7.9.3 Morrison Formation Confining Unit

Overlying the Sundance and Unkpapa aquifers is the Morrison Formation. The Morrison is a shale layer approximately 100 feet thick, which serves as an underlying confining unit between the Inyan Kara and the Sundance aquifers (and the Unkpapa where it exists). A core sample was collected from the upper

Morrison; results of geotechnical testing indicate that the shale has a relatively low vertical permeability of about 6.0×10^{-5} feet/day.

7.9.4 Inyan Kara Aquifer

The Inyan Kara aquifer is the principal aquifer in the region. Locally, the Cretaceous Inyan Kara Group is consistent with its regional characteristics and is composed of two formations: the Lakota (Fuson and Chilson members) and Fall River. In general, the Inyan Kara consists of interbedded sandstone, siltstone, and shale. Based on several measured outcrop sections within the Dewey Quadrangle, the Inyan Kara Group averages 350 feet thick. The Fuson member of the Lakota, underlying the Fall River, varies in thickness from 40 to 70 feet. Throughout most of the region, the Fuson is expected to be an effective interaquifer confining unit. Locally, however, results of aquifer tests at the project site indicate that the Fuson Shale is not an effective barrier in some locations. It is possible that, "interaquifer connection here could result from as-yet-unidentified structural features or old open exploration holes". As such, the Inyan Kara is treated in this report as one aquifer with the Fall River and Lakota representing sub-aquifers. The Inyan Kara is confined above by the Graneros Group, a thick sequence of dark shale that varies in thickness from zero (0) feet where the Inyan Kara crops out to more than 500 feet thick in the plains, preventing the vertical migration of water between the Inyan Kara and alluvial aquifers.

7.9.5 Graneros Group Confining Unit

The Graneros Group is composed of several geologic formations including the Skull Creek, Newcastle, Mowry, and Belle Fourche. The group acts as a single unit that confines the Inyan Kara aquifer. In the PAA, the thickness of the Graneros is zero (0) at the outcrop but increases westward to more than 500 feet thick. A core sample was collected from the lower Skull Creek shale; results of geotechnical testing indicate that the shale has a very low vertical permeability of 1.5×10^{-5} ft/day.

7.9.6 Alluvial Aquifers

For the purpose of this report, the alluvial aquifers in the vicinity of the project site consist of any saturated alluvial material along Pass Creek, Beaver Creek, and the Cheyenne River. In general, the thickness of the alluvial material varies from zero (0) to 25 feet, although it can reach 40 feet. Based on water level measurements in five alluvial piezometers, the upper 10 to 15 feet of the alluvium is unsaturated. The alluvial material is typically unconfined although localized areas of confinement may exist where weathered shale and other material has slumped on top of the alluvium. Groundwater level data and groundwater samples were collected for laboratory analyses.

7.9.7 Groundwater Flow

The hydrologic investigation of this site included measurement of water levels in wells completed in the Inyan Kara aquifer, the overlying alluvial aquifer, and the underlying aquifer (Sundance/Unkpapa). The data were used to assess groundwater flow direction as indicated by groundwater elevations, to construct potentiometric surfaces and to calculate hydraulic gradient. Data collection and analyses were started in 2007 and are ongoing in order to document pre-development conditions and changes in potentiometric head before, during, and after operations. Appendix 7.9-A lists water level data collected from wells completed in the Inyan Kara aquifer during this study.

Water level data were collected as follows:

- Monthly water levels were measured in wells listed in Table 7.9-1. This table summarizes the wells by formation as determined by well completion information or, if well completion information was not available, through analyses of water quality information. These wells were selected to provide water level data upgradient and downgradient of the proposed mine areas.
- Water levels were measured in monitoring wells listed in Table 7.9-1 as follows:

- Static water levels were measured at most wells prior to sample collection with regard to a reference elevation, usually a mark on the well or on a permanent structure above or near to the well.
- When possible, free-flowing wells were measured with a 15 lb/in^2 (psi) or 30 psi N.I.S.T.-certified pressure gauge.
- The well was shut in and the pressure was allowed to stabilize before a reading was recorded.
- Pressure values were recorded to within at least 0.1 psi and typically to within 0.01 psi.
- Wells with subsurface water levels were measured using an electric water level tape with measurements reported to within at least one tenth of a foot and typically to within a hundredth of a foot.
- Exceptions to this procedure included:
- Domestic wells that could not be accessed at the well head or were behind a pressure tank (well numbers 7, 8, 13, 16, 18, 42).
- Free-flowing wells that could not be sealed due to leaks caused by corrosion and age (wells 2, 635, 4002).
- Free-flowing wells that could not be sealed due to poor valve fittings or cracked valves (well 696).
- Free-flowing wells where existed the possibility of rupturing a line when pressurized due to age (well 7002).
- Wells that contained pumps and pump tubing making it difficult to retrieve a water level tape (well 619).
- Water level measurements from pumping and monitoring wells that were taken during the aquifer tests are given in the aquifer test report (see Appendix 7.9-B).

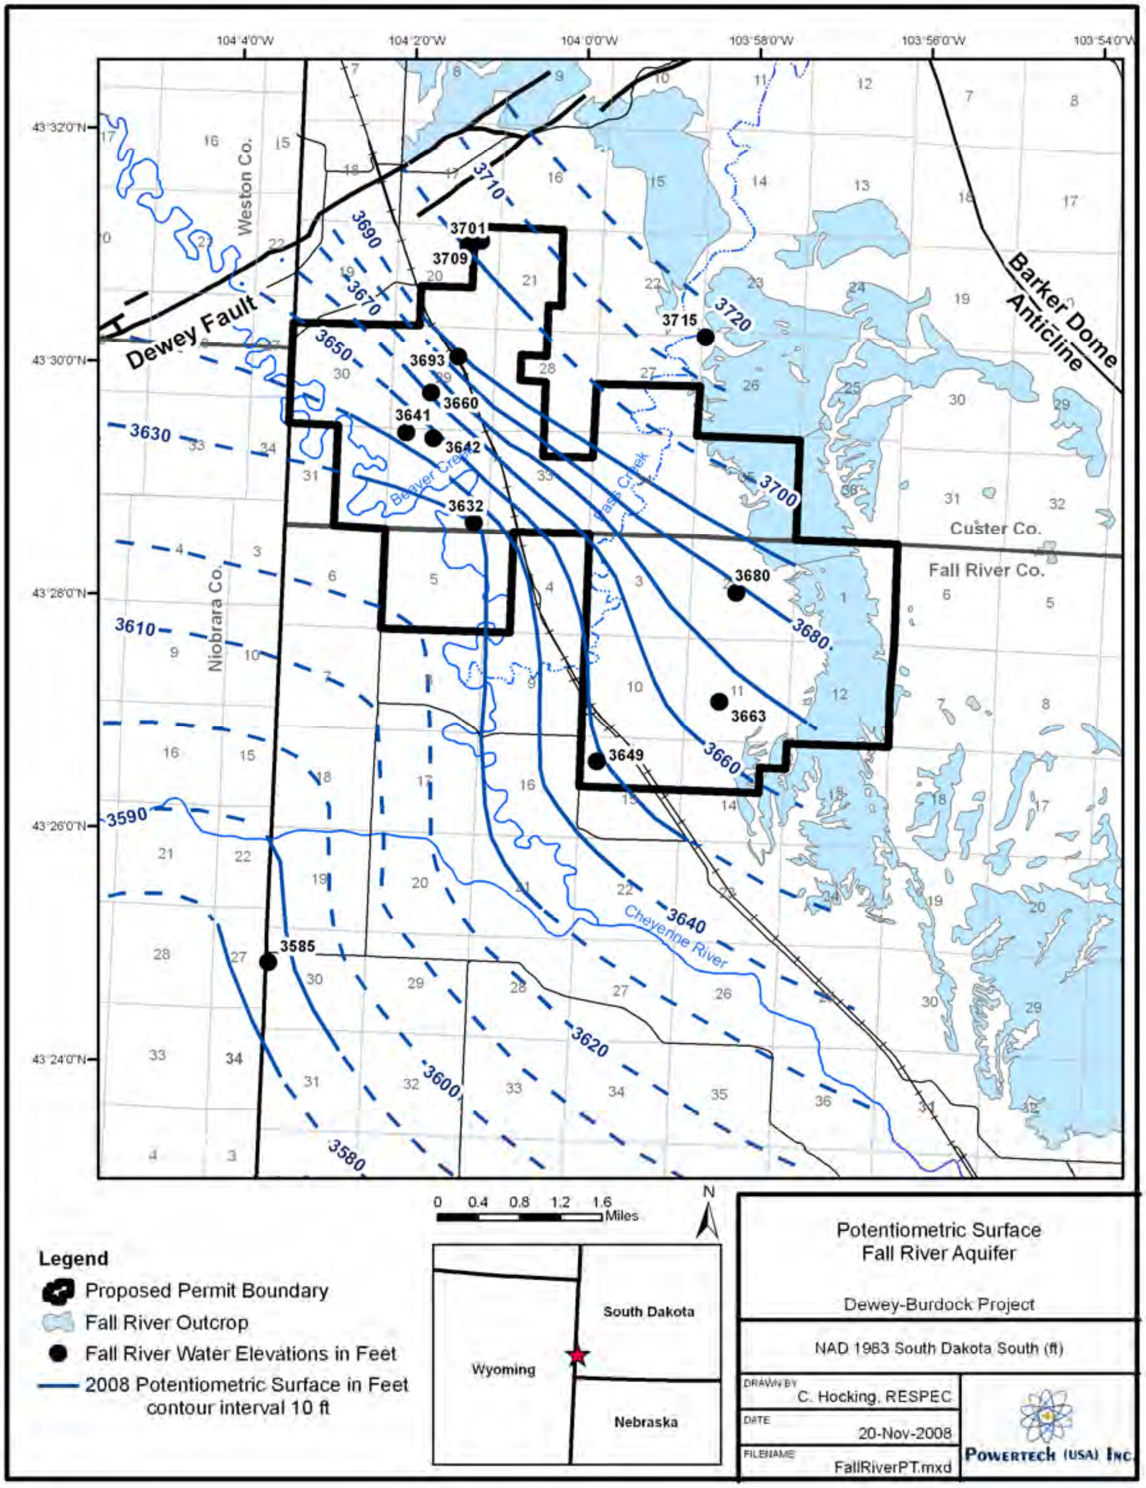
Maps of the current potentiometric surface for the Fall River (Figure 7.9-1), Lakota (Figure 7.9-2), and Unkpapa (Figure 7.9-3) aquifers have been generated using water level data collected in the area from September 2007 through June 2008 (Appendix 7.9-A). The regional USGS map *"Potentiometric Surface of the Inyan Kara Aquifer in the Black Hills Area, South Dakota"* was used as a general guide in areas where water level data are unavailable (Strobel et al., 2000).

The general pattern of groundwater flow is, as expected, away from the highlands and is similar for all aquifer local units. Throughout the southwestern Black Hills including the study area, the groundwater gradient is generally southwestward. Analyses of regional information indicate that similar flow patterns should exist from ground surface to the Precambrian aquifer.

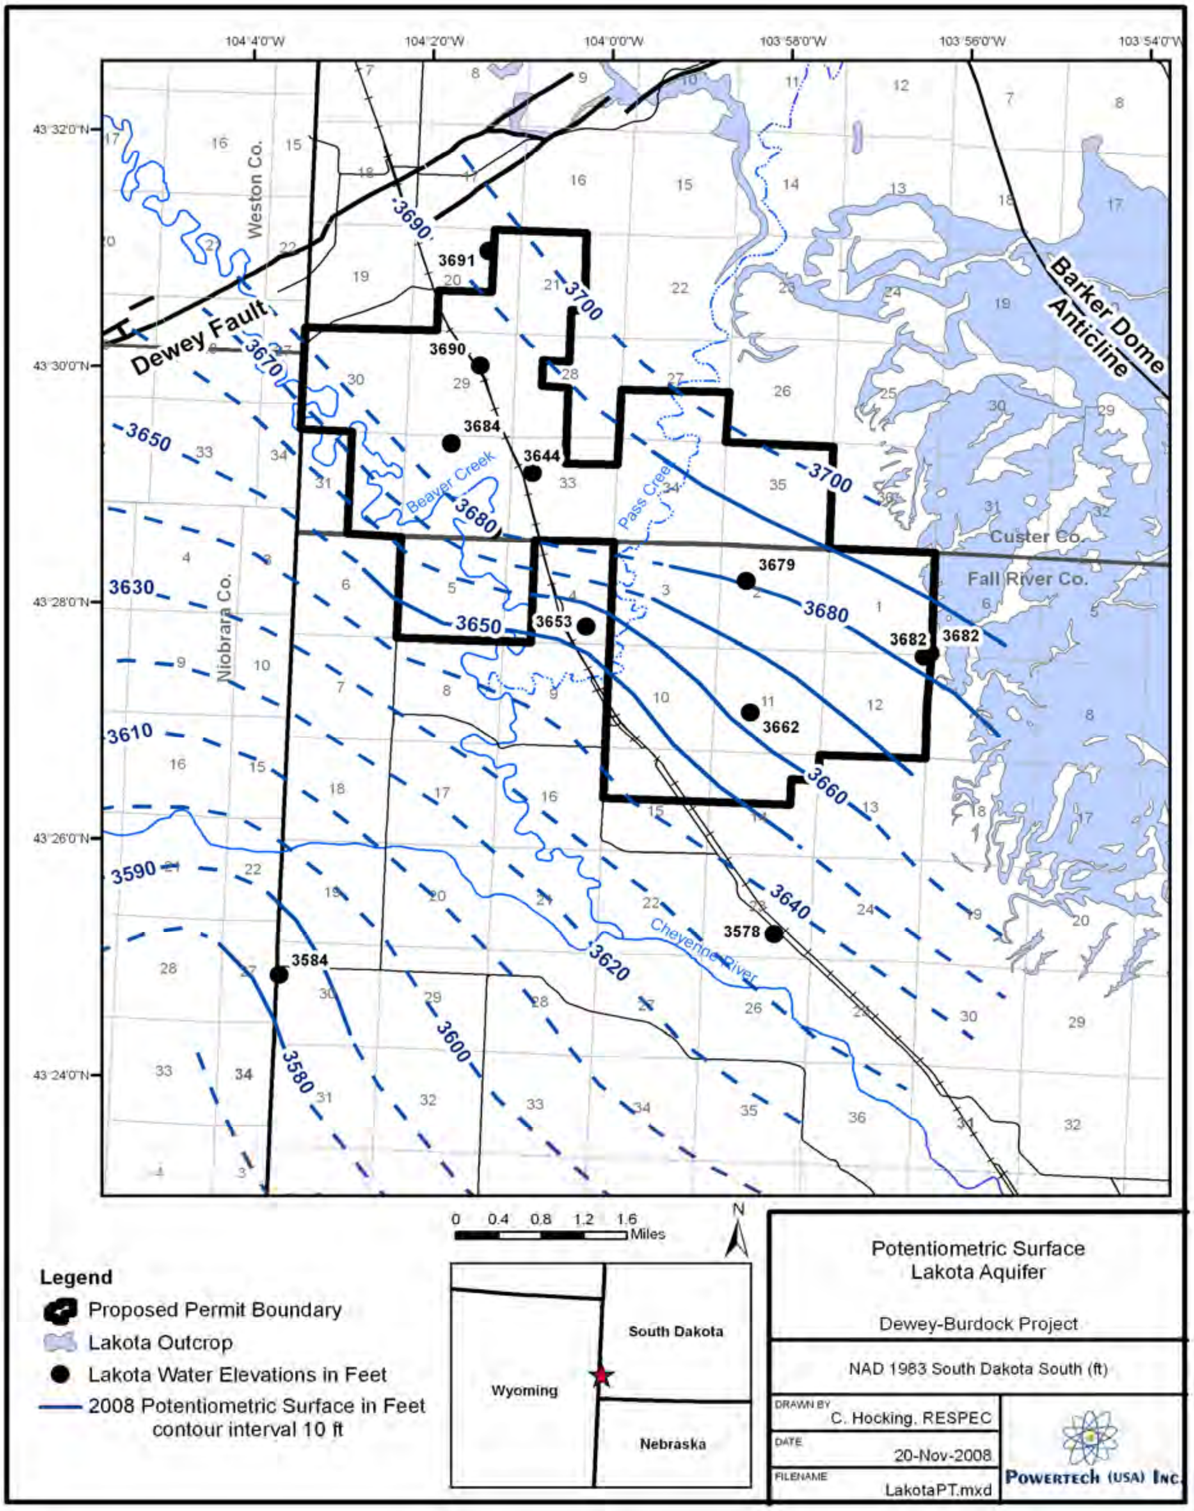
Appendix 7.9-A summarizes water levels and elevations measured in Fall River and Lakota wells. These paired wells, plus data gathered during the pumping tests, provide the capability to assess site-specific aquifer connections as follows:

- Analyses of water levels reported from wells near recharge or outcrop areas demonstrate that water levels in the Lakota Formation are somewhat higher than in the Fall River.
- With increasing distance from the recharge areas, this difference in head appears to diminish.
- Review of pumping test data from the Dewey area indicates that pumping a well located within the Fall River does not impact the Lakota heads. Where the Fuson is an ineffective confining unit, water could flow upward into the Fall River Formation. Because of this uncertain connectivity, the Fall River and Lakota Formations are considered to be one aquifer (the Inyan Kara aquifer) in this report.



Note: Potentiometric surface based on average water level values at the project site. Contours are dashed where approximate.

Figure 7.9-1 Potentiometric Surface of the Fall River Aquifer



Note: Potentiometric surface based on average water level values at the project site. Contours are dashed where approximate.

Figure 7.9-2 Potentiometric Surface of the Lakota Aquifer

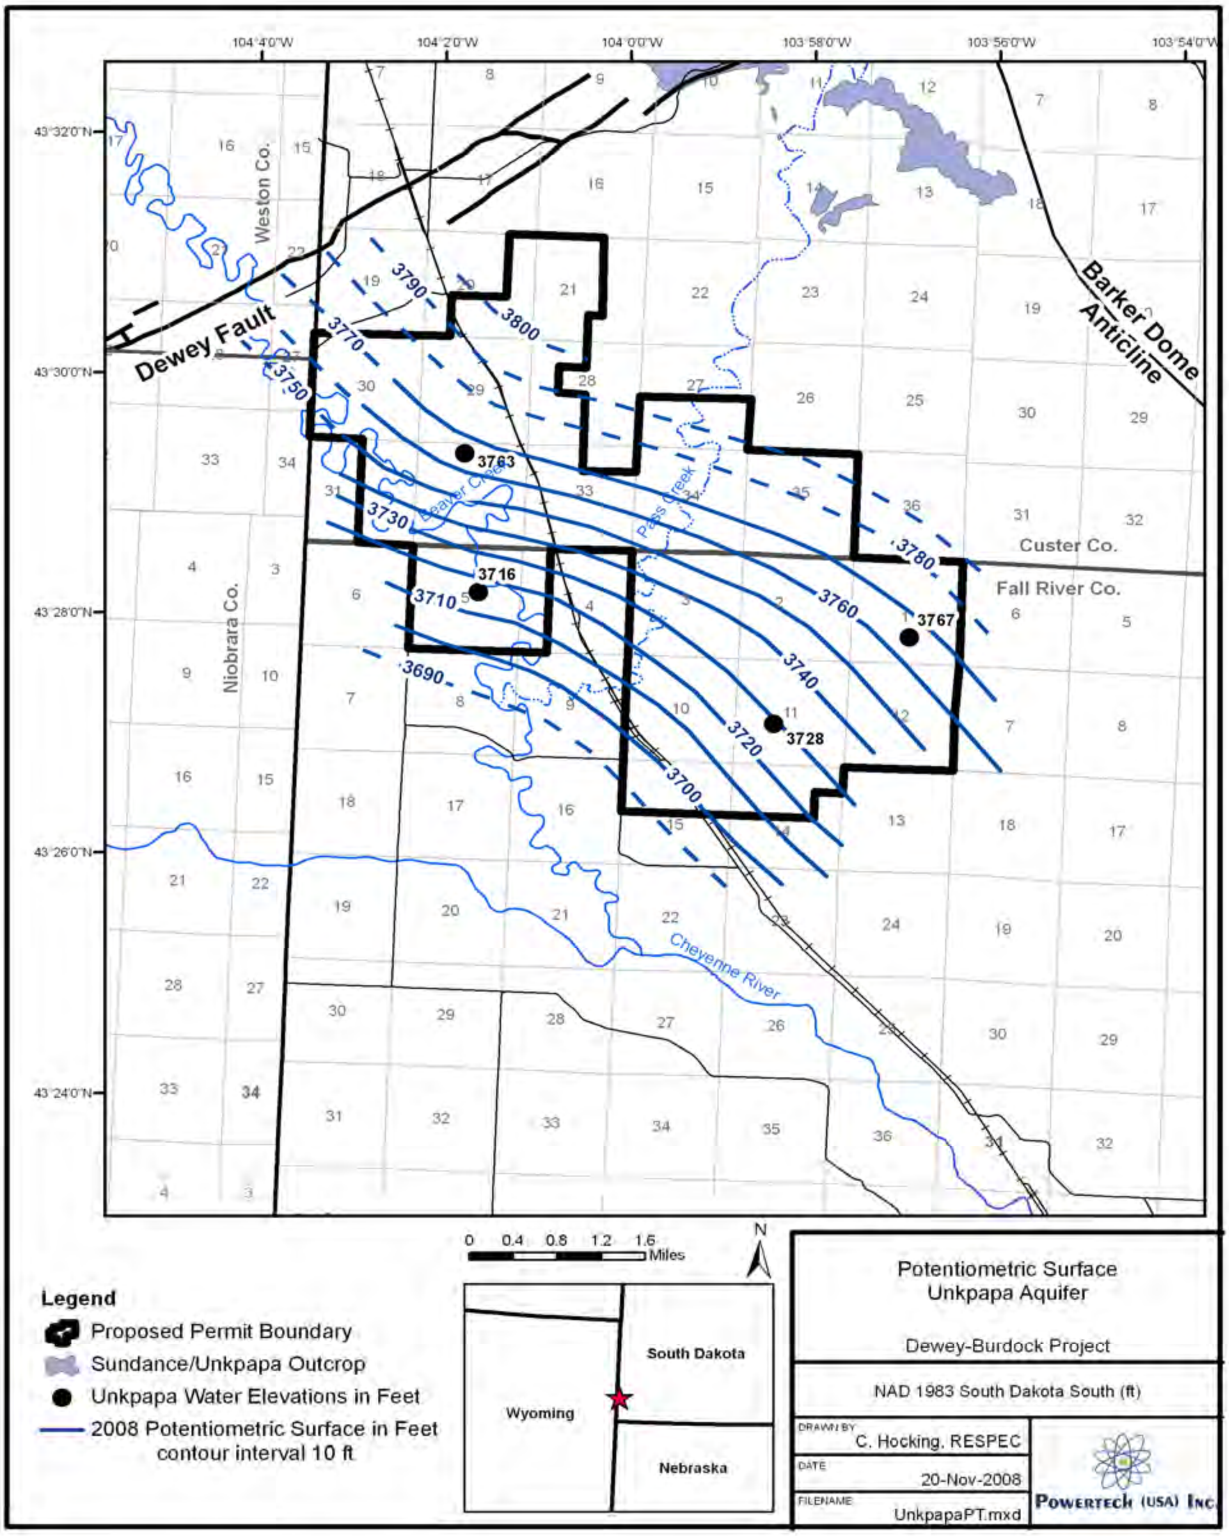


Figure 7.9-3 Potentiometric Surface of the Unkpapa Aquifer

If the aquifer materials were homogeneous, groundwater would flow in the direction of the gradient. Within the PAA, it is likely that groundwater flow is partially controlled by interfingering channels and heterogeneous beds.

North of the site, the Dewey Fault is believed to affect groundwater movement. At its greatest, the Dewey Fault has more than 400 feet of offset. This offset would place the Lakota Formation, south of the fault, against the impermeable Spearfish Formation north of the fault. Based on TVA's Dewey pumping test, the fault behaved as an impermeable zone and resulted in drawdown greater than would occur in an infinite aquifer (Boggs, 1983).

It is common practice in the area to allow artesian wells to continuously flow to prevent freezing. Undoubtedly, this practice has resulted in a decline in potentiometric head over decades.

7.9.8 Site Groundwater Recharge and Discharge

Groundwater may recharge or discharge from the site under the following mechanisms:

- Recharge via infiltration of precipitation
- Discharge via evapotranspiration
- Recharge or discharge to streams or springs
- Recharge or discharge into overlying or underlying hydrogeologic units
- Recharge or discharge along the Dewey fault zone
- Discharge to wells
- Recharging groundwater flow into the study area
- Discharging groundwater flow out of the study area.

The first three mechanisms are limited to unconfined alluvium in stream channels with depths less than 100 feet. The remaining mechanisms apply from the highland outcrop to the PAA, as the units transition from unconfined outcrops to confined units. Recharge to confined groundwater is primarily from precipitation recharge at the outcrop. Most of this recharge occurs at the highland outcrops, as shown in Figure 7.9-4. Based on data from Carter et al. (2001), an average of 0.3 to 0.5 inches of precipitation (2 to 3 percent of 16 in/yr) that falls each year recharges the Inyan Kara aquifer.

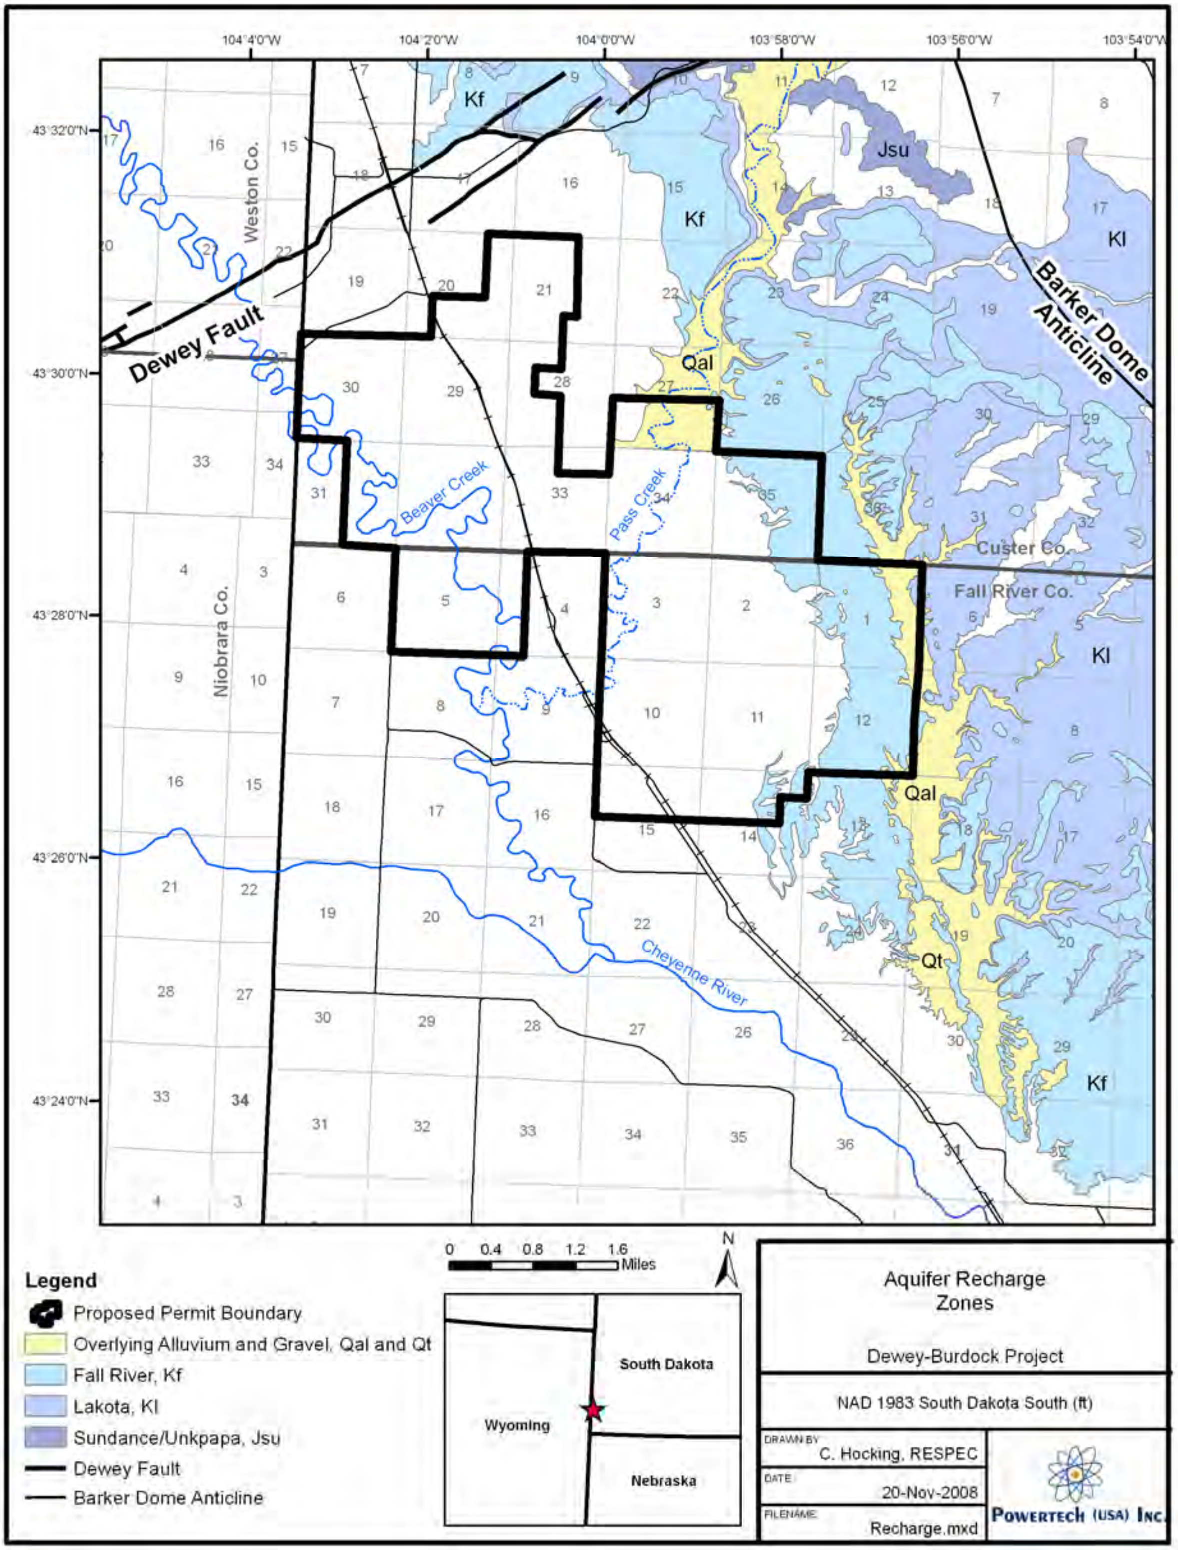

Figure 7.9-4Aquifer Recharge Zones

7.9.9 Site-Specific Groundwater/Surface Water Interactions

Near the PAA, there are several possible modes of interaction between groundwater and surface water. Groundwater becomes surface water where free-flowing artesian wells discharge into surface water impoundments. There are no natural springs in the PAA. The only other major avenue for interchange is along the alluvium where Pass Creek crosses the Inyan Kara outcrop. Here, the alluvium may either gain or lose flow to the underlying aquifer. There is currently no stream loss data for Pass Creek to quantify this interaction.

7.9.10 Hydraulic Properties of the Inyan Kara at the Project Site

This section describes past and recent aquifer pumping tests and the insight on hydraulic properties that were gained.

7.9.10.1 Summary of Previous Pump Test Results

The TVA conducted groundwater pumping tests from 1977 through 1982 as part of a uranium mine development project near the towns of Edgemont and Dewey, South Dakota. TVA produced two summary pumping test reports, "Analysis of Aquifer Tests Conducted at the Proposed Burdock Uranium Mine Site" (Boggs and Jenkins, 1980) and "Hydrogeologic Investigations at Proposed Uranium Mine near Dewey, South Dakota" (Boggs, 1983). In addition, TVA prepared a Draft Environmental Statement (DES) for the proposed Edgemont Uranium Mine in 1979.

TVA first conducted two unsuccessful tests in 1977 at the Burdock test site. The results of the 1977 tests were considered inconclusive because of various problems including questionable discharge measurements, some observation wells improperly constructed, and some pressure gauges malfunctioned. No data from the 1977 tests are currently available.

TVA conducted three successful pumping tests, two in 1979 near the current Burdock Project Area, and one in 1982 about two miles north of the current PAA. The results of these successful tests are described in separate sections, below. However, no data for these tests, in particular electronic records of drawdown, are available, other than information contained in the reports.

7.9.10.1.1 Dewey Proposed Action Area

The Dewey test was conducted in 1982 northeast of Dewey Road at the location shown on Figure 7.9-5. The test consisted of pumping in the Lakota formation for 11 days at an average rate of 495 gallons per minute [gpm]. The test developed the following information:

- Transmissivity of the Lakota averaged about 4,400 gallons per day per foot (gpd/ft) which is equivalent to 590 feet squared per day (ft^2/day).
- Storativity of the Lakota was about 1.0×10^{-4} (dimensionless).
- There was response between the Fall River and Lakota formations through the intervening Fuson shale-siltstone member that was manifested at relatively late time (3000 to 10000 minutes).
- The vertical hydraulic conductivity of the Fuson aquitard using the Neuman-Witherspoon ratio method (Neuman and Witherspoon, 1973) was 2×10^{-4} ft/day; storativity of the Fuson Member was not determined and specific storage was about 7×10^{-7} ft^{-1}.
- A barrier boundary, or a decrease in transmissivity due to lithologic changes with distance from the test site, or both, were observed; a possible geologic feature corresponding to a barrier was noted to be the Dewey Fault Zone, located about 1.5 miles north of the test site, where the Lakota and Fall River formations are structurally offset.

POWERTECH (USA) INC.

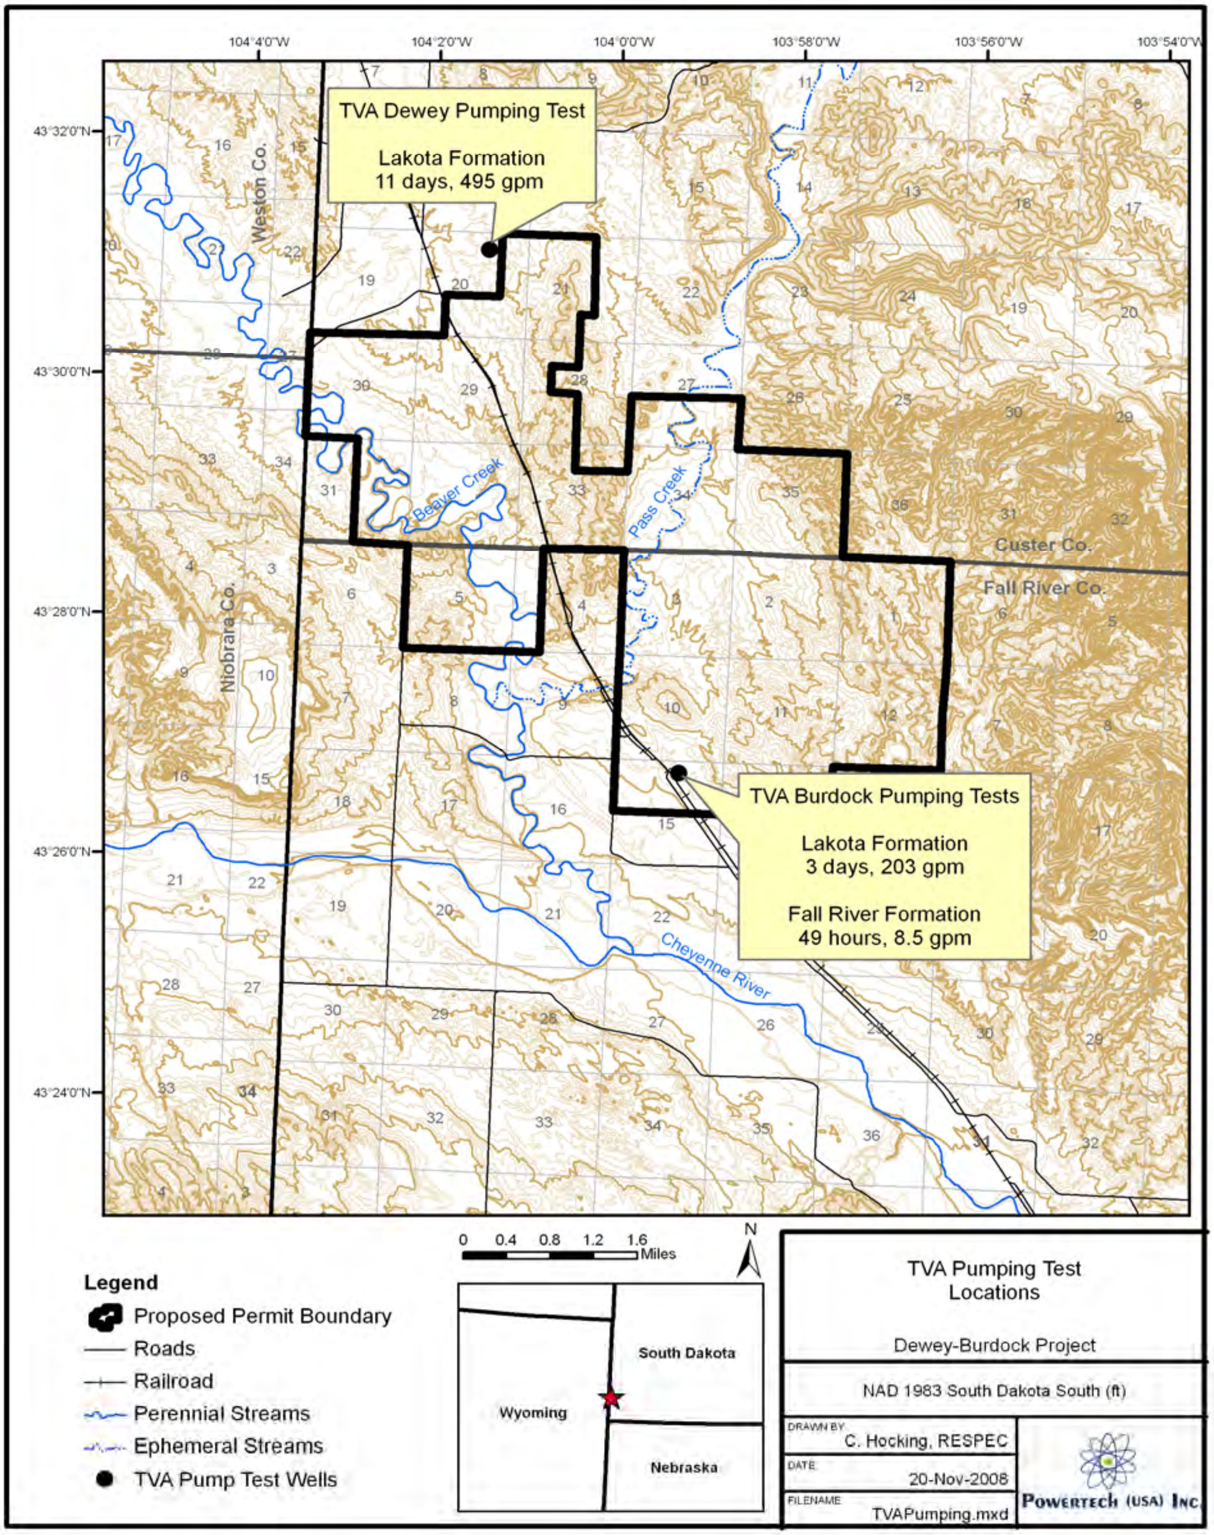

Figure 7.9-5 Location of Historical TVA Pumping Tests

7.9.10.1.2 Burdock Project Area

The Burdock tests were conducted in 1979 near Dewey Road at the location shown on Figure 7.9-5. The Burdock tests consisted of separate pumping tests from the Lakota (Chilson) and Fall River Aquifer, respectively in April and July of 1979. The tests used the same pumping well with packers to alternately isolate screens open to the respective formations. Test durations were 73 hours for the Lakota test and 49 hours for the Fall River test. Pumping rates were about 200 gpm from the Lakota aquifer and 8.5 gpm from the Fall River. The reason for the unexpected low pumping rate from the Fall River aquifer was not specified in the TVA report.

The tests developed the following information:

- Interpreted transmissivity of the Lakota was based on analysis of later time data and inferred decreasing transmissivity with distance from the test site due to changes in lithology; overall transmissivity averaged about 1,400 gpd/ft (190 ft^2/day) and storativity about 1.8 x 10^4 (dimensionless); maximum transmissivity from early time data was about 2,300 gpd/ft (310 ft^2/day).
- Transmissivity of the Fall River averaged about 400 gpd/ft (54 ft^2/day) and storativity about 1.4 x 10^5 (dimensionless).
- There was communication between the Fall River and Lakota formations through the intervening Fuson shale-siltstone member; leaky behavior was observed in the Fall River formation and believed to exist in Lakota although “leakage effects in the Lakota drawdown data are masked by the conflicting effect of a decreasing transmissivity in site vicinity” (p. 16 in Boggs and Jenkins, 1980).
- The vertical hydraulic conductivity of the Fuson aquitard the Neuman-Witherspoon ratio method (Neuman and Witherspoon, 1973) ranged from 10^{-3} to 10^{-4} ft/day; storativity was not determined, and specific storage was assumed to be about 10^{-6} ft^{-1}.

7.9.10.1.3 2008 Pumping Tests

In 2008 pumping tests were performed at both the project areas, along with laboratory tests on related core samples, to determine aquifer properties at the site. A work plan (Knight Piésold, 2008a) was prepared and distributed to interested representatives of state and federal agencies, including the South Dakota DENR and the EPA.

A detailed description of the aquifer testing methodology and analysis of the results are contained in the aquifer test report (Knight Piésold, 2008b), Appendix 7.9-B. The report results are briefly summarized in the following sections.

7.9.10.1.4 Burdock Project Area

7.9.10.1.4.1 Summary of Burdock Pumping Test Results

A summary of aquifer parameters for the 2008 Burdock pumping test (conducted in the Chilson member of the Lakota formation) and related laboratory core testing is as follows:

- Nine determinations of transmissivity (Table 7.9-2) ranged from 120 to 223 ft^2/day with the median value of 150 ft^2/day.
- Four storativity determinations (Table 7.9-2) ranged from 6.8 x 10^{-5} to 1.9 x 10^{-4} with the median value of 1.2 x 10^{-4}.
- The radius of influence of the pumping test determined by a distance-drawdown plot was 2,100 ft.
- The pumping well in the lower Lakota formation was determined to be moderately efficient: 80 to 83 percent by the empirical distance-drawdown method and 65 percent the USGS (Halford and Kuniansky, 2002) theoretical method.

- Laboratory measurements of horizontal and vertical hydraulic conductivity (Table 7.9-3) were made on sandstone layers similar to that tested in the pump test; measured horizontal hydraulic conductivity ranged from 5.9 to 9.1 ft/d, the mean value was 7.4 ft/d and the mean ratio of horizontal to vertical hydraulic conductivity in Burdock area sandstone was 2.47:1.
- Laboratory measurements of horizontal and vertical hydraulic conductivity (Table 7.9-3) were made on shale layers from the two major confining units for the Lakota formation in the pump test area with the following results:
  - Fuson Shale: the laboratory core data indicate vertical permeabilities of about 2×10^{-7} to 1×10^{-8} cm/sec (average 2.7×10^{-4} ft/d) for shale samples from within the Fuson member overlying the Lakota formation.
  - Morrison Shale: the laboratory core data for the shales in the underlying Morrison formation indicate vertical permeabilities of 9×10^{-9} to 3×10^{-8} cm/sec (average 6.0×10^{-5} ft/d).
- The range of hydraulic conductivities determinable from test transmissivities was 0.9 to 15.0 ft/d, which is considered an appropriate range that is also verified by the sandstone core sample results falling in the middle of the range; it is noted that the lower end of the hydraulic conductivity range is probably appropriate for use with the entire formation thickness (shale layers included) and the upper end represents the most permeable sandstone layers such as the ore zone areas tested in the pump test.

Average Lakota Sand K_h, K_v								7.4	3.0

7.9.10.1.4.2 Burdock Pumping Test Conclusions

The Burdock pumping test in 2008 may be directly compared to the 1979 TVA test for the Lakota (Chilson) aquifer as the tests were nearly at the same location (Figure 7.9-5). The average transmissivity and storativity values determined from the TVA tests were 190 ft^2/d and 1.8×10^{-4} (see p. 17 in Boggs and Jenkins, 1980). Comparing median transmissivity of 150 ft^2/d and storativity of 1.2×10^{-4}determined in the 2008 test to the TVA test, the new aquifer parameters for the lower Lakota are respectively about 80 and 70 percent of the 1979 results. Because transmissivity and storativity depend on aquifer thickness, comparing the results suggests that there may be some scaling effect between the tests due to the differing lengths of screened intervals.

Therefore, the 1979 TVA test transmissivity of 190 ft^2/d is considered representative of the entire Lakota aquifer for a regional application, such as a groundwater flow model where an average hydraulic conductivity of about 1 ft/d over a thickness of 170 ft could be specified. The 2008 test provides specific data at the operational-scale of a prospective ISL well field where local hydraulic conductivities of up to 15 ft/d could be specified for the most permeable ore zones horizons.

Within the Lakota formation, vertical communication throughout the entire formation is indicated by the delayed response at the upper Lakota observation well (11-19). The 160-minute delay in response at the upper Lakota observation well 11-19 is attributed to lateral and vertical anisotropy due to the shale interbeds seen on the conceptual stratigraphic cross-sections for the pump test site (Knight Piésold, 2008b). The extent and continuity of the shale interbeds are unknown. Whether the shale interbeds in the Lakota aquifer are sufficiently thick and continuous to serve as vertical confinement for ISL operations will probably need to be evaluated by analyzing cores from borings as well fields are drilled.

The 2008 test indicates that the lower and upper portions of the Lakota formation behave as a single, confined, leaky aquifer. Confinement and leakage from the overlying Fuson member is evident in the matches to the Hantush-Jacob type curves seen most clearly at observation wells 11-14C and 11-2. These results are more definitive than the 1979 TVA test where confined, leaky behavior for the Lakota was predicted but not demonstrated with curve match results.

Hydraulic communication through the Fuson member between the Lakota and Fall River aquifers is evidenced by the response at observation well 11-17, screened in the lower Fall River formation. The first response in the lower Fall River is interpreted as a Noordbergum effect where water levels monitored above the pumping zone aquitard temporarily increased due to three-dimensional deformation caused by ground water withdrawal from a confined aquifer (Hseigh, 1997). The Noordbergum effect appears characteristic of the Inyan Kara formation based on its occurrence in a 1985 pumping test in the Eastern Black Hills near Wall, South Dakota (Rahn, 1985) and also the previous TVA test at the Burdock site (Boggs and Jenkins, 1980). However, drawdown continued at the Fall River observation well 11-17, indicating that leakage was established through the underlying Fuson formation.

The laboratory core data indicate an average vertical permeability of 9.3×10^{-8} (2.7×10^{-4} ft/d) for shale samples from within the Fuson member. The shale core permeability values are about one to two orders of magnitude less permeable than the pumping test values determined in the 1979 TVA test at Burdock, where the vertical hydraulic conductivity of the Fuson aquitard was calculated using the Neuman-Witherspoon ratio method to be about 10^3 ft/day (see pg. (i) in Boggs and Jenkins, 1980).

The potentiometric surface in the Fall River aquifer is close to that in the Lakota aquifer at the Burdock pump test site, indicating some local connection between the two formations through the intervening Fuson member. In other locations in the Inyan Kara, the Fuson member is known to have sandstone layers that are downcut into the Lakota member (Gott et al., 1974). Therefore, determining the degree of vertical confinement for ISL operations by the Fuson will probably need to be evaluated by analyzing cores from borings as well fields are drilled, and with well field-scale pumping tests that are proposed to be conducted prior to startup of each particular mine unit.

The aquifer tests in 1979 and 2008 indicate that the Lakota formation is a confined aquifer with a leaky confining layer, which is demonstrably the Fuson member. The laboratory core data for the shales in the underlying Morrison formation indicate an average vertical permeability of 2.1×10^{-8} cm/sec (6×10^{-5} ft/d). Together with the pump test data, the core data indicate that the underlying Morrison formation and overlying Fuson member can serve as aquitards for ISL operations.

For the Lakota sandstone, the laboratory core data indicate an average horizontal hydraulic conductivity of 7 ft/d, and as high as 9.1 ft/d. Interpretation of the test results calculates that horizontal permeability may be as great as 15 ft/d throughout one of the ore zones. Within the lower Lakota formation, the test results indicate transmissive response between pumping and observation wells up to 250 feet apart with 17 feet of drawdown. Response was nearly 3 feet of drawdown at 1,290 ft distance. This indicates the aquifer was stressed to produce good quality analytical results.

7.9.10.1.5 Dewey Project Area

7.9.10.1.5.1 Summary of Dewey Pumping Test Results

A summary of aquifer parameters for the 2008 Dewey pumping test (conducted in the Fall River formation) and related laboratory core testing is as follows:

- Ten determinations of transmissivity (Table 7.9-4) ranged from 180 to 330 ft^2/day with the median value of 255 ft^2/day.
- Five storativity determinations (Table 7.9-4) ranged from 2.3×10^{-5} to 2.0×10^{-4} with the median value of 4.6×10^{-5}.
- The radius of influence of the pumping test determined by a distance-drawdown plot was 5,700 feet.
- The pumping well in the Fall River formation was determined to be highly efficient: 93 to 95 percent by the empirical distance-drawdown method and 81 percent by the USGS (Halford and Kuniansky, 2002) theoretical method.
- Laboratory measurements of horizontal and vertical hydraulic conductivity (Table 7.9-4) were made in core sample from the sandstone layer similar to that tested in the pump test; measured horizontal hydraulic conductivity was 6.1 ft/d, and the ratio of horizontal to vertical hydraulic conductivity was 4.5:1.
- Laboratory measurements of horizontal and vertical hydraulic conductivity (Table 7.9-4) were made on shale samples from the two major confining units overlying and underlying the pump test area with the following results:
  - Skull Creek shale: laboratory core data for the shale sample from the overlying Skull Creek formation indicate a vertical permeability of 5.4×10^{-9} cm/sec (1.5×10^{-5} ft/d).
  - Fuson Formation: laboratory core data for the shale sample from the underlying Fuson formation indicate a vertical permeability of 6.2×10^{-9} cm/sec (1.8×10^{-5} ft/d).

7.9.10.1.6 Dewey Pumping Test Conclusions

The Dewey pumping test in 2008 in the Fall River aquifer is not directly comparable to the 1982 TVA test because the underlying Lakota aquifer was tested in 1982. As demonstrated above for the Lakota aquifer (Section 7.9.10.1.3.1), a scaling effect may be assumed between total formation transmissivity and storativity (i.e., regional-scale) and the 2008 operational-scale test. However, there are several lines of evidence that the 2008 test transmissivity and storativity results are representative of the entire Fall River aquifer at the Dewey test site, as follows:

- Thickness of the sandstone layer screened by the pumping well is about one-half the total formation thickness (see drawings 4.1 and 4.2 in Appendix 7.9-B).

- Response at the stock tank well (GW-49at 1,400 ft distance) was within the acceptable range for a confined aquifer; this is interpreted to indicate that the effects of partial penetration (due to elevation differences between the pumping well screen and the observation well open to the upper half of the aquifer) were diminished at the 1,400 ft distance and 40 minute response time.
- The delay in response at the upper Fall River observation well 32-9C was a relatively brief, 11 minutes (see Table 4.2 in Appendix 7.9-B), compared to 160 minutes in the Burdock test; together with (2) above, these responses suggest that the vertical anisotropy due to shale interbeds overlying the lower sandstone layer does not extend laterally for more than about 1,400 feet.

The 2008 test indicates that the lower and upper sandstone portions of the Fall River formation behave as a single, confined, aquifer with some form of lateral barrier due to changing lithology, such as a channel boundary. The TVA test in 1982 observed a barrier boundary in the underlying Lakota formation which was attributed to either a change in lithology or the Dewey Fault zone. Apparently, both the Lakota and Fall River formations in the general Dewey Project Area are highly transmissive and show barrier boundaries. These test results are more definitive than the 1982 TVA test concerning the proximity of the barrier boundary, because the 2008 radius of influence was about one mile compared to greater than two to three miles distance to the fault zone.

Vertical flow throughout the entire Fall River Formation is indicated by the delayed response at the upper Fall River observation well (32-9C). Within the Fall River Formation, the 11 minute delay in response at the upper observation well is attributed to lateral and vertical anisotropy due to the shale interbeds seen on the conceptual stratigraphic cross-sections for the pump test site (see Drawings 4.1 and 4.2 in Appendix 7.9-B). The extent and continuity of the shale interbeds are not known. Whether the shale interbeds in the Fall River Aquifer are sufficiently thick and continuous to serve as vertical confinement for ISL operations will need to be evaluated by analyzing cores from borings as well fields are drilled.

Leakage from a confining layer, presumably the Fuson member, was observed in the 1982 TVA test of the Lakota formation. However, the leakage was observed only relatively late in the TVA tests, at 3,000 to 10,000 minutes, with a much greater pumping rate (495 gpm) and radius of influence. The large-scale vertical hydraulic conductivity value of 2 x 10^{-4} ft/day (7.1 x 10^{-8} cm/sec) determined in the 1982 TVA regional test at Dewey using the Neuman-Witherspoon ratio method is sufficiently impermeable to be considered an aquitard or aquiclude.

Hydraulic flow through the Fuson member between the Fall River and underlying Lakota aquifers is not indicated by the 2008 response at observation well 32-10. The 2008 test demonstrates that vertical leakage through the Fuson may not occur over a mile-wide radius. As described in Section 5.2.4, the Lakota and Fall River aquifers at the Dewey test site appear to be locally hydraulically isolated by the intervening Fuson member with nearly 40 feet head difference. The laboratory core data indicate a very low vertical permeability of 6.2 x 10^{-9} cm/sec (1.8 x 10^{-5} ft/d) for the shale sample from within the Fuson shale member.

The laboratory core data for the shale sample from the Skull Creek formation, overlying the Fall River formation, indicate a very low vertical permeability of 5.4 x 10^{-9} cm/sec (1.5 x 10^{-5} ft/d), also appropriate for an aquitard or aquiclude.

For the Fall River sandstone, the laboratory core data indicate a horizontal hydraulic conductivity of 6.1 ft/d, and interpretation of the test results calculates that horizontal permeability may be as great as 17 ft/d throughout one of the ore zones. Within the lower Fall River formation, the test results indicate transmissive, rapid response (two to three minutes) between pumping and observation wells up to 467 feet apart with nearly 10 feet of drawdown. Response was nearly 9 feet of drawdown at 1,400 feet distance. This indicates the aquifer was stressed to produce good quality analytical results.

7.9.10.1.7 Hydraulic Connection of Aquifers at the Project Site

Regionally, the Inyan Kara is a confined aquifer. At the project site, the Graneros Group shale serves as the overlying confining unit that prevents upward migration. There are also no major aquifers above the Inyan Kara from which connection could occur. Below the Inyan Kara, the Morrison Formation serves as a relatively impermeable confining unit. At the project site, results from recent pump tests show that the Morrison effectively confines the Unkpapa aquifer below since no measurable drawdown in the Unkpapa was observed while pumping in the Inyan Kara. However, a minor amount of communication between the Inyan Kara and underlying aquifers (including the Unkpapa, Sundance, and Minnelusa) may occur in yet undiscovered areas where the Morrison is thin or absent or along undiscovered breccia pipes. For a more detailed discussion on the regional and site hydrostratigraphic units see Sections 7.8.1 and 7.9.

Within the Inyan Kara, the Fuson member of the Lakota is expected to be an effective interaquifer confining unit. Results of aquifer tests at the project site indicate that the Fuson Shale is not an effective barrier in some locations (Boggs and Jenkins, 1980). Locally unidentified structural features or more likely old, unplugged exploration holes enhance this interaquifer connection. The exact location of these potentially unplugged holes is undeterminable. However, over 95 percent of exploration holes never penetrated deeper than the lower Lakota and upper Morrison, so this potential venue of connection is limited to within the Inyan Kara itself. Flow from these open holes could potentially reach the ground surface, although swelling of overlying clays and associated collapse are probably preventing this situation from occurring. Because of such interaquifer connection, the Inyan Kara is treated in this report as one aquifer with the Fall River and Lakota representing sub-aquifers.

Re: Concurrence for Occupancy Request for the Dewey-Burdock Project
Custer and Fall River Counties, South Dakota

Dear Ms. Kimball:

Information requested by the BLM in its July 8, 2014, request for additional information regarding the Dewey-Burdock Project Plan of Operations includes a concurrence for occupancy request in accordance with 43 CFR §3715.2. This letter constitutes the request by Powertech (USA), Inc. (Powertech) regarding concurrence for occupancy of BLM-administered lands within the Dewey-Burdock Project boundary in Custer and Fall River Counties, South Dakota.

The Dewey-Burdock Project is a proposed uranium *in situ* recovery (ISR) facility licensed by the U.S. Nuclear Regulatory Commission (NRC) under source and byproduct materials license SUA-1600, which was issued April 8, 2014 (NRC ADAMS Accession No. ML14043A392). In accordance with 43 CFR §3715.2, Powertech seeks concurrence for installing facilities and fences on BLM-administered lands. The response to the July 8, 2014, request for additional information, provided under separate cover, describes the facilities and project infrastructure planned on BLM-administered surface during the initial year of project development and potential future facilities planned during the life of the project. These include power lines, access roads, culverts, ISR production/injection wells, monitor wells, buried pipelines, and well field fences. The concurrence for occupancy is requested since these facilities are proposed to remain on BLM-administered lands for longer than 14 days. Proposed facilities are necessary for the extraction and beneficial use of uranium mineral resources and constitute substantially regular work items that are integral to the search for and development of mineral deposits occurring within the Dewey-Burdock Project boundary.

Consultation with BLM before beginning occupancy is being satisfied through submittal of this request, information provided in the October 2009 Plan of Operations, and through discussions held during teleconferences with BLM representatives Phil Perlewitz, Nate Arave, Dan Benoit, and Marian Atkins on May 29, 2014, and BLM representatives Nate Arave, Greg Fesko, Linda Reder, and others on August 6, 2014.

As required by 43 CFR §3715.3-2, Powertech submits the following information to support its request for concurrence for occupancy of public lands as defined in 43 CFR §3715.0-5.

- Overview maps of the project area were provided with the 2009 Plan of Operations as Exhibits 1.1-1 and 1.1-2. Maps showing facilities planned on BLM-administered lands during the initial year of project development and potential future facilities were provided as Exhibits 1.1-3 and 1.1-4, respectively, in Powertech's response to BLM's July 8, 2014, request for additional information, provided under separate cover.

- The purpose of the fencing proposed on BLM-administered lands is to control livestock and human access to well fields. Signs will be posted in accordance with NRC license requirements at the access point for each well field warning of the potential for radioactive material. The purpose of the proposed access roads and culverts is to provide safe passage for employees and visitors to project facilities. The purpose of the monitor wells and potential future well fields is to conduct monitoring, uranium extraction, and groundwater restoration operations. The purpose of the pipelines is to transport various ISR solutions between the well fields and the central processing plant (CPP, which is not located on BLM-administered lands) during uranium extraction and groundwater restoration operations. The purpose of the power lines is to provide electricity to the well field equipment (e.g., production well pumps and header houses).

- The access roads, culverts, power line, fences, and wells all involve observable, on-the-ground activities that BLM may physically inspect and verify in accordance with 43 CFR §3715.7.

POWERTECH (USA) INC.

- Appropriate, maintained and operable equipment will be used.

- Powertech does not plan to install fences and gates that will completely exclude the general public from crossing BLM-administered lands. Fences are proposed only around the immediate perimeter of proposed well fields as shown on Exhibit 1.1-4 provided with Powertech's response to BLM's July 8, 2014, request for additional information. It is noted that BLM-administered lands occurring within the Dewey-Burdock Project boundary are surrounded by private property and cannot be accessed without permission from private landowners.

- Powertech estimates that construction of the initial well field, CPP, and ancillary facilities including wastewater treatment and storage ponds (which will not be located on BLM-administered lands) will take 1-2 years. Well fields will be developed sequentially along with supporting infrastructure, including header houses and pipelines. Uranium recovery operations are anticipated to last approximately 8 years, with groundwater restoration occurring as soon as practicable following production in each wellfield. Wellfield decommissioning will proceed sequentially as production and restoration activities are completed in each well field and will be followed by decommissioning of the processing facilities. The maximum project life is anticipated to be up to about 20 years.

- Powertech employees will be present at the Dewey-Burdock Project site 24 hours a day, 7 days a week during operations.

If additional information related to Powertech's request for concurrence for occupancy is required, please do not hesitate to contact me at 303-790-7528.

Sincerely,

John Mays

John M. Mays, P.E.
Chief Operating Officer

Dewey-Burdock Project
Pond Design Report

Executive Summary

This report provides the preliminary pond design for the land application option and for the deep well disposal option at the Dewey-Burdock project. These designs have been completed following United States Nuclear Regulatory Commission (USNRC) Regulatory Guide 3.11, NUREG 1569, 10 CFR Part 40, Appendix A, Criterion 5 and State of South Dakota Administrative Rule 74:29:11:23.

Land Application Option

The land application option includes six categories of ponds:

- Radium settling ponds containing bleed and restoration water and used to settle radium out of solution
- Outlet ponds used to intercept treated water from the radium settling ponds and to store stormwater falling on the radium settling ponds
- Storage ponds used to store treated water during the non-irrigation season
- A central plant pond containing brine produced at the Burdock Plant site
- Spare ponds used for emergency containment should the radium settling or central plant ponds fail
- Spare storage ponds used for emergency containment should any of the storage ponds fail, or portions of the land application system become temporarily inoperable

The design makes allowance for the following:

- Two radium settling ponds, one each at the Dewey and Burdock having a storage capacity of 39.4-acre-ft each
- Two outlet ponds, one each at the Dewey and Burdock sites having a storage capacity of 4.9-acre-ft each
- Two sets of storage ponds:
    - A system of four ponds constructed at the Dewey Site each having a storage capacity of 63.8-acre-ft

- A system of four ponds constructed at the Burdock Site each having a capacity of 63.8-acre-ft

- Two spare storage ponds, one each at the Dewey and Burdock Sites having a storage capacity of 63.8-acre-ft each
- A central plant pond at the Burdock site having a capacity of 36.2-acre-ft
- Two spare ponds, one each at the Dewey and Burdock Sites having a capacity of 39.4-acre-ft each

<u>Deep Well Disposal Option</u>

The deep well disposal option includes five categories of ponds:

- Radium settling ponds, containing bleed water and restoration water and used to settle radium out of solution
- Outlet ponds used to intercept treated water from the radium settling ponds and to store stormwater falling on the radium settling ponds
- Surge ponds, containing water that has been treated and which is to be pumped to the disposal wells
- Spare ponds, used for emergency containment should any of the ponds fail
- A central plant pond containing brine produced at the Burdock Plant site

The design makes allowance for the following:

- Two radium settling ponds, one each at the Dewey and Burdock having a storage capacity of 15.9-acre-ft each
- Two outlet ponds, one each at the Dewey and Burdock sites having a storage capacity of 5.1-acre-ft each
- Two surge ponds, one each at the Dewey and Burdock sites having a storage capacity of 8.4-acre-ft each
- A central plant pond at the Burdock site having a capacity of 15.9-acre-ft
- Two spare ponds, one each at the Dewey and Burdock sites having a capacity of 15.9-acre-ft each

The ponds have been designed to store water reporting to them while maintaining 3 feet (ft) of freeboard. The geometry and storage characteristics of the radium settling ponds have also been checked to verify that they will allow the efficient removal of radium from solution.

The radium settling, spare and central plant ponds will be provided with the following lining system:

- An 80-milli-inch (mil) high density polyethylene (HDPE) primary liner
- A 60-mil-HDPE secondary liner
- A 1-ft-thick clay liner below the secondary liner
- A geonet drainage layer sandwiched between the primary and secondary HDPE liners
- A leak detection sump and access port system

All other ponds will contain treated water that is either to be used for land application or deep well disposal. These ponds will include a single 40-mil-HDPE liner underlain by a 1-ft-thick clay liner.

The results of the stability analyses calculated for the embankments using three different methods of analysis; Bishop Method, Janbu Method, and Morgenstern-Prices Method indicate that the slopes are stable under both static and MCE seismic loading conditions.

Precipitation falling in the land application areas will be contained within those areas and in evaporation pans located adjacent to them, from where it will evaporate. The Soil Plant Air Water (SPAW) modeling indicates that there will be no percolation beyond the base of the soil profile from the land application system and therefore no potential impact to groundwater. Also the underlying Graneros Group provides a low permeability barrier to any potential seepage from land application.

The ponds provided for the land application design all have larger storage volumes than the ponds provided for the deep well disposal option, which is discussed in Section 4.0. Therefore, the land application ponds would also operate satisfactorily for deep well disposal.

Powertech (USA) Inc.
Dewey-Burdock Project
Pond Design Report

1.0 Introduction

1.1 Background

Knight Piésold was retained by Powertech (USA) Inc. to design the water containment storage ponds associated with land application and deep well disposal at the proposed Dewey-Burdock Project. The project is located in the Fall River and Custer Counties in South Dakota, on the southwest flank of the Black Hills uplift. It will involve in situ leaching to recover uranium from the Fall River and Lakota Formations.

This report describes the results of the pond design and stability, seepage and seismic analysis in accordance with NRC Regulatory Guide 3.11, NUREG 1569, 10 CFR Part 40 Appendix A, Criterion 5 and South Dakota Administrative Rule 74:29:11:23. These regulatory requirements are provided in Appendix A. The ponds have been sized to store and treat water resulting from the in situ leach process, stormwater runoff from the land application areas, and the 100-year, 24-hour design storm event.

1.2 Limitations and Disclaimer

This report titled Dewey-Burdock Project Pond Design Report has been prepared by Knight Piésold and Co. (Knight Piésold) for the exclusive use of Powertech (USA) Inc. (Client). No other party is an intended beneficiary of this report or the information, opinions, and conclusions contained herein. Any use by any party other than the Client of any of the information, opinions, or conclusions is the sole responsibility of said party. The use of this report shall be at the sole risk of the user regardless of any fault or negligence of the Client or Knight Piésold.

The information and analyses contained herein have been completed to a level of detail commensurate with the objectives of the assignment and in light of the information made available to Knight Piésold at the time of preparation. This report and its supporting documentation have been reviewed and/or checked for conformance with industry-accepted norms and applicable government regulations. Calculations and computer simulations have been checked and verified for reasonableness, and the content of the report has been reviewed for completeness, accuracy, and appropriateness of conclusions. To the best of the information and belief of Knight Piésold, the information presented in this report is accurate to within the limitations specified herein.

2.0 Site Investigation

2.1 General

Knight Piésold carried out a site investigation at the Dewey-Burdock site during July 2008. The investigation was limited to excavating test pits and was targeted at obtaining the following:

- Parameters required for land application modeling
- Engineering characteristics of the soils for pond design

Eleven test pits were excavated as part of the investigation, ranging in depth form 6 to 13 ft. Five of the test pits were excavated at the Dewey Site, with the remainder being excavated at the Burdock Site. The locations of the test pits in relation to land application and irrigation, and to deep well disposal options are illustrated in Figures 2.1-1 and 2.1-2, respectively. Test pit logs are included in Appendix B. Samples obtained from the test pits were tested at Knight Piésold's geotechnical laboratory in Denver for the following properties:

- Visual classification
- Particle size distribution
- Specific gravity
- Natural moisture content
- Dry bulk density
- Atterberg limits
- Compaction testing
- Triaxial testing
- Flexible wall permeability

Samples were also sent to an outside laboratory where they were evaluated for sodium absorption ratio (SAR) and soil organic carbon (SOC).

2.2 Subsurface Conditions

The soils underlying the site consist primarily of lean clays, lean clays with sand, fat clays, and fat clays with sand. Clayey gravel was encountered in test pit TP03 and sandy lean clay was encountered in test pits TP04 and TP08. Bedrock, where encountered, consisted of either claystone or shale. Results from the laboratory tests indicate that the materials are suitable for the construction of the proposed ponds. Stability analysis results that are presented in Sections 3.11 and 4.9 confirm this.

Test pit logs are provided in Appendix B, and geotechnical laboratory test results are provided in Appendix C.

3.0 Land Application Pond Design

3.1 SPAW Modeling Assumptions

The design of the land application system was developed based on modeling using the SPAW model, as described further in Appendix D. Two land application areas, one at the Dewey site and one at the Burdock site will be used. The total irrigated area at any given time at the Dewey site would be 315 acres, consisting of four 50-acre pivots, four 25-acre pivots, plus one 15-acre pivot. In addition, there would be one 50-acre pivot and one 15-acre pivot on standby (total pivots at Dewey is five 50-acre pivots, four 25-acre pivots, and two 15-acre pivots). Pumping at Dewey would occur for 24 hours every day from March 29 to May 10 at a rate of 297 gallons per minute (gpm); from May 11 to September 24 at a rate of 653 gpm; and from September 25 to October 31 at a rate of 297 gpm.

The total irrigated area at any given time at the Burdock site would also be 315 acres (six 50-acre pivots plus one 15-acre pivot). In addition, there would be two 25-acre pivots and one 15-acre pivot on standby. The total pivots at Burdock would be six 50-acre pivots, two 25-acre pivots, and two 15-acre pivots. Pumping at Burdock would also occur for 24 hours on every day from March 29 to May 10 at 297 gpm, from May 11 to September 24 at a rate of 653 gpm, and from September 25 to October 31 at a rate of 297 gpm.

Precipitation falling in the land application areas will be contained within those areas and in evaporation pans located adjacent to them, from where it will evaporate. The SPAW modeling indicates that there will be no percolation beyond the base of the soil profile from the land application system and therefore no potential impact to groundwater. Also the underlying Graneros Group provides a low permeability barrier to any potential seepage from land application (reference Plates 315, 335, 337 and 338).

Four single-lined impoundments (ponds) would be constructed at the Dewey site for the temporary storage of the irrigation water. Each pond will be 465 ft wide x 465 ft long x 30 ft deep including 3 ft of freeboard, with an operating capacity of 61.8-acre-ft. In addition to the storage ponds, double-lined radium settling and spare ponds with leak detection, and single-lined spare storage and outlet ponds will also be constructed at Dewey. The radium settling pond and spare ponds will be 880 ft long x 200 ft wide x 25.5 ft deep, including 3 ft of freeboard, and will have an operational storage of 39.4-acre-ft. The outlet pond will be 280 ft wide x 162 ft long x 14 ft deep including 3 ft of freeboard, and will have an operational storage of 4.9-acre-ft. The spare storage pond will be geometrically identical to the storage ponds.

Four single-lined impoundments (ponds) would be constructed at the Burdock site for the temporary storage of the irrigation water. Each pond will be 465 ft wide x 465 ft long x 30 ft deep including 3 ft of freeboard, with an operating capacity of 61.8-acre-ft. In addition to the storage ponds, double-lined radium settling, spare, and central plant ponds with leak detection, and single-lined spare storage and outlet ponds will also be constructed at Burdock. The radium settling and spare ponds will be 880 ft wide x 200 ft long x 25.5 ft deep, including 3 ft of freeboard, and will have an operational storage of 39.4-acre-ft. The central plant pond will be 362 ft wide x 362 ft long x 25 ft deep including 3 ft of freeboard, and will have an operational storage of 36.2-acre-ft. The outlet pond will be 280 ft wide x 162 ft long x 14 ft deep including 3 ft of freeboard, and will have an operational storage of 4.9-acre-ft. The spare storage pond will geometrically identical to the storage ponds

The ponds provided for the land application design all have larger storage volumes than the ponds provided for the deep well disposal option, which is discussed in Section 4.0. Therefore, the land application ponds would also operate satisfactorily for deep well disposal.

3.2 Design Flows

Three water streams resulting from mining activities report to the ponds:

- Bleed water from the production wells
- Restoration water from the restoration wells
- Process water from the plant

Bleed and restoration water is pumped to the radium settling ponds where it is treated before overflowing into the outlet pond and pumped to the storage ponds where it is used for land application. Process water from the central processing plant (CPP) is pumped to the central plant pond, where it is stored. Allowance has been made for all ponds to store water resulting from the 100-year, 24-hour storm event while maintaining 3 ft of freeboard.

3.2.1 Production Well Bleed Water

The in situ leach process includes for up to 3 percent of the water pumped from the production wells to be bled from the system. Total production water is approximately 4,000 gpm, resulting in a bleed flow of approximately 120 gpm. This water will be pumped to the radium settling ponds.

3.2.2 Wellfield Restoration Water

This water, having a flow rate of approximately 500 gpm, will be used to flush the mineralized target zone following uranium recovery. Once it returns to the surface, the water will be pumped to the radium settling ponds.

3.2.3 Process Water

The uranium recovery process will result in a brine stream of approximately 12 gpm. Allowance has been made for some of this water to be stored in a central plant pond.

3.2.4 Precipitation

All precipitation falling on the land application areas will be stored within those areas where it will either evaporate or infiltrate into the soil. Water falling directly on the pond surfaces will be stored in the ponds and used for land application.

3.3 Pond Design Requirements

Active storage requirements for the radium settling, outlet, storage, and central plant ponds are provided below. In addition to the active storage requirements and the design storm event, all ponds will be provided with 3 ft of freeboard. The catchment areas of the ponds will be minimized by grading all roads away from them, and by providing stormwater diversions to prevent water from upstream catchments from reporting to them.

Figure 3.3-1 provides the Burdock Plant Site Plan and Figures 3.3-2 and 3.3-3 includes the pond cross sections.

Figure 3.3-4 provides the Dewey Plant Site Plan and Figures 3.3-5 and 3.3-6 include the pond cross sections.

3.3.1 Radium Settling Ponds

Radium is settled out of solution by adding barium chloride to the water. Co-precipitation of radium occurs when natural sulfate (SO_4) in the water combines with radium (Ra) and barium (Ba) to form $RaBaSO_4$. The requirements for efficient settlement of solids out of a solution have been incorporated into the design of the ponds and include the following:

- Sufficient retention time for the settlement of radium out of solution
- Providing adequate surface area to prevent the development of large surface currents
- Providing a pond geometry or arrangement that will prevent short circuiting of flows through the pond

Radium is settled out of solution by adding barium chloride to the water. Co-precipitation of radium occurs when natural sulfate (SO_4) in the water combines with radium (Ra) and barium (Ba) to form $RaBaSO_4$. All discussions in the following sections, therefore, refer to the settlement of radium barium sulfate.

3.3.1.1 Retention Time and Storage

Water in the ponds must be retained for sufficient length of time to allow radium barium sulfate to settle out of solution. A literature survey of radium settling ponds indicated that typical retention times range from eight to 14 days. A retention time of 14 days has been adopted for this project. This requires that the ponds have a minimum storage volume of 38.4-acre-ft. In addition, the ponds are expected to accumulate 790-cubic-ft per year (ft^3/year) of radium barium sulfate sludge. For a 10-year project life, this will amount to 0.18-acre-ft of storage. The design allows identical radium settling ponds to be constructed at Dewey and Burdock Sites, capable of storing 39.4-acre-ft each, allocated as follows:

- 39.2-acre-ft for bleed and restoration water
- 0.2-acre-ft for sludge accumulation

Stormwater will overflow into the outlet pond, which has been sized to accommodate the 100-year, 24-hour storm event from both itself and the radium settling pond.

3.3.1.2 Surface Area

To promote settling, the pond surface area should be large enough to prevent significant surface currents from developing. Should these develop, they could keep the radium barium sulfate in suspension. They could also result in short circuiting, with water flowing directly from the pond inlet to the outlet.

The literature survey indicated that a minimum area of 0.6 acres should be allowed for every 100 gpm of flow. For a flow of 620 gpm, this results in area of 3.72 acres with the designed ponds having a water surface area of 3.85 acres.

3.3.1.3 Pond Geometry

Unless baffles are provided, the length of a settling pond should ideally be at least four times its width. The radium settling ponds have a crest length of 880 ft and a width of 220 ft, satisfying this requirement.

3.3.2 Outlet Ponds

Identical outlet ponds have been designed for the Dewey and Burdock Sites. They have been sized to accommodate one day's production water, equating to 2.7-acre-ft, and precipitation from the 100-year, 24-hour storm event falling on both the radium settling and outlet pond.

The ponds have been designed to store the following:

- 2.7-acre-ft for treated irrigation water
- 1.7-acre-ft for the 100-year, 24-hour design storm event falling on the radium settling pond
- 0.4-acre-ft for the 100-year, 24-hour design storm event falling on the radium settling pond

3.3.3 Storage Ponds

Outflow from the storage ponds to land application areas exceeds water inflow during the period of land application (March 29 to October 31). However, water generated during the remainder of the year needs to be stored until it can be used for land application. Total storage requirements were modeled using the SPAW Model, and were calculated to be 216.4-acre-ft at both the Dewey satellite plant site and the Burdock central processing plant site. Allowance has been made for an additional 27.5-acre-ft of storage at each site to allow for the possibility that the start of the land application may be delayed.

The design allows four storage ponds to be constructed at both the Dewey and Burdock Sites, for a total of eight ponds, each capable of storing 63.8-acre-ft, allocated as follows:

- 61.8-acre-ft for treated irrigation water
- 2-acre-ft for the 100-year, 24-hour design storm event

3.3.4 Central Plant Pond

The central plant pond is located at the Burdock Site, and has been sized to accommodate a discharge of 10.81 gpm over a period of two years, equating to 34.9-acre-ft.

The pond has been designed to store the following:

- 35-acre-ft for brine from the CPP
- 1.2-acre-ft for the 100-year, 24-hour design storm event

3.3.5 Spare Ponds

The spare ponds have been designed to be identical to the radium settling ponds, which are the largest double-lined ponds in the system. The spare ponds are located adjacent to the radium settling pond. They have been designed to accommodate water from any of the radium settling or central plant ponds, should the ponds fail.

A spare storage pond has been designed at both the Dewey and Burdock sites to provide emergency containment for the single-lined storage and outlet ponds.

3.4 Water Flow Configurations

Water will be routed through the storage ponds to maximize retention time. Figure 3.4-1 provides the Burdock Plant Site Flow Diagram and Figure 3.4-2 provides the Dewey Plant Site Flow Diagram.

3.5 Pond Lining Systems

The lining system for the radium settling, spare and central plant ponds will consist of the following:

- An 80-mil-textured primary HDPE liner.
- A 60-mil-smooth secondary HDPE liner.
- A 12-inch-thick compacted clay liner, having a maximum permeability of $1x10^{-7}$ cm/sec. This liner will be constructed below the secondary HDPE liner.
- A geonet sandwiched between the primary and secondary HDPE liners.

The outlet and storage ponds will contain treated water that will be used for land application. The liner requirement on these ponds is therefore less stringent, and will consist of the following:

- An 40-mil-textured HDPE liner.
- A 12-inch-thick compacted clay liner, having a maximum permeability of $1x10^{-7}$ cm/sec. This liner will be constructed below the HDPE liner.

3.6 Leak Detection Systems

The radium settling, spare and central plant ponds will include a geonet drainage layer installed between the primary and secondary HDPE liners. The geonet will drain into a leak detection sump. A minimum grade of 2 percent will be maintained across the bottom of the ponds to facilitate the drainage of water into the leak detection sump should a leak develop. A leak detection access port and pump will be provided at the sump to allow any water collecting there to be pumped out and monitored. Pipes feeding into the double-lined ponds will be dual contained, with the carrier and containment pipes being connected to the primary and secondary HDPE liners, respectively. The leak detection system is shown on Figure 3.6-1.

3.7 Foundation Preparation

Foundation preparation on the ponds will include the following:

- Removing vegetation, existing structures and unsuitable foundation materials
- Subgrade preparation
- Site grading

More detail on the items listed above is provided in Table 3.7-1.

Table 3.7-1 – Foundation Preparation Requirements

Item	Description
Vegetation	Clear and grub vegetation
Structures	Remove any existing structures
Surface soils	- Strip organic soil matter for a minimum of 10 ft beyond the pond embankment limits. - Place the stripped soil in temporary stockpiles for final reclamation. - Stockpiles should be located as close to the stripped areas as possible. - Proposed stockpile locations are indicated on Figures 3.7-1, 3.3-1, and 3.3-3.
	Scarify, moisture condition and compact the top 6-inches of the stripped ground surface in fill areas to a minimum of 90 percent of the maximum Modified Proctor Dry Density (ASTM D 1557).
Site Grading	Undertake site grading cut and fill. Compact graded materials to a minimum of 90 percent of the maximum dry density (ASTM D 1557) within ± 2 percent of the optimum moisture content.

3.8 Embankment Drainage

An embankment drainage system will be installed in the outer face of all embankments to prevent the outer toe of the embankment from becoming saturated should a HDPE liner system fail. Water collected by the drain system will be conveyed to a sump from where it will be pumped back to the ponds.

3.9 Pond Connectivity

All storage ponds will be connected via spillways. The radium settling and spare ponds will also be connected to the outlet pond via a spillway. The proposed flow of water through the ponds system is shown on Figures 3.4-1 and 3.4-2.

3.10 Pond Seepage Analysis

Seepage analyses were undertaken for the outer embankments of the ponds to model the phreatic surface through the outer embankments of the ponds should the HDPE liners fail. The phreatic surface determined from the seepage analysis was then used to model embankment slope stability for that condition.

All ponds will be HDPE lined, with the HDPE liner being underlain by a 1-ft-thick clay liner. Negligible seepage is expected from them under normal operating conditions.

3.10.1 Material Properties

Flexible wall permeability tests were undertaken on both undisturbed and remolded samples collected from site. The results were further subdivided depending on which site the samples were collected at, and are summarized in Table 3.10-1.

Table 3.10-1 – Permeability Test Results

Site	Test Type*	No. of Samples	Permeability (cm/sec)			
			Min	Max	Average	Median
Dewey	Undisturbed	12	$2.30x10^{-7}$	$4.90x10^{-4}$	$7.63x10^{-5}$	$2.80x10^{-5}$
	Remolded	11	$3.70x10^{-9}$	$2.90x10^{-6}$	$5.45x10^{-7}$	$8.70x10^{-8}$
Burdock	Undisturbed	10	$4.20x10^{-8}$	$5.70x10^{-4}$	$8.03x10^{-5}$	$7.20x10^{-6}$
	Remolded	8	$7.90x10^{-9}$	$9.30x10^{-5}$	$1.87x10^{-5}$	$7.55x10^{-6}$

*Undisturbed samples were collected using Shelby tubes; remolded samples were compacted to 95 percent of maximum dry density.

The median undisturbed permeabilities have been assumed for the in situ soils, while the median remolded permeabilities have been assumed for the embankments. In addition, regulatory requirements specify that a 1-ft-thick clay liner having a maximum permeability of $1x10^{-7}$ be used below the HDPE liners in the ponds. Material from the pond excavation will be selected to meet this criterion. If necessary, borrow areas will be developed to source this material.

Sand used in the embankment drainage system was assumed to have a permeability of $5x10^{-4}$ cm/sec.

3.10.2 Analysis

For the seepage analysis, it was assumed that the HDPE liners in the ponds fail completely, with the 1-ft-thick clay liner providing the only barrier to seepage through the embankment. The seepage analysis was completed using the GeoStudio 2007 software package.

3.11 Pond Stability Analyses

Stability analyses on the pond embankments were completed using the GeoStudio 2007 software package. The sections selected for the analysis are located at the highest points of the embankments.

3.11.1 Analyses

The following analyses were conducted on each of the ponds:

- A static stability analysis, assuming that the liners are intact (no phreatic surface in the embankment)

- A pseudostatic analysis, assuming the liners are intact and modeling the Maximum Credible Earthquake (MCE) acceleration
- A static analysis, assuming that the liners have completely failed, allowing a phreatic surface to develop in the embankment
- A pseudostatic analysis, assuming that the liners have completely failed, allowing a phreatic surface to develop in the embankment, and modeling the MCE acceleration

3.11.2 Soil Strengths

Soil strengths were obtained from three tri-axial tests that were conducted on material samples collected during the site investigation. The results from these tests are provided in Table 3.11-1.

Table 3.11-1 – Material Strength Characteristics

Site	Sample Number	Angle of Friction (°)	Cohesion (ksi)	Description
Dewey	TP 02-7	25.0	0.10	Lean clay with sand
Burdock	TP 08-6	28.5	0.06	Sandy lean clay
	TP 09-4	27.0	0.15	Lean clay with sand

Test pits TP 08-6 and TP 09-4 are located close to the Burdock Site, with test pit TP 02-7 being located close to the Dewey Site. As the material strength values obtained from test pit TP 09-4 are lower than those obtained from test pit TP 08-6, those values were used for the analyses undertaken at the Burdock Site. The material strength values obtained from test pit TP 02-7 were used for the analyses undertaken on the ponds at the Dewey Site.

3.11.3 Material Densities

In situ material densities were obtained from undisturbed samples collected during the site investigation. The densities of embankment materials were obtained from compaction tests undertaken on samples collected from site. Results for the Dewey and Burdock Sites are summarized separately in Table 3.11-2.

Table 3.11-2 – Soil Densities

Site	Test Type	No. of Samples	Moist Soil Density (pcf)			
			Min	Max	Average	Median
Dewey	Undisturbed	12	86.3	113.3	98.3	97.6
	Compaction test	7	120.4	124.2	123.0	124.0
Burdock	Undisturbed	11	92.4	101.0	97.9	98.3
	Compaction test	6	123.7	130.7	127.4	126.7

Median undisturbed densities have been assumed for in situ soils, while the median densities from the compaction tests have been assumed for the embankments and clay liners.

3.11.4 Seismic Ground Acceleration Values

MCE ground accelerations were obtained from the document "Dewey-Burdock Project, Application for NRC Uranium Recovery License, Fall River and Custer Counties, South Dakota, Technical Report," dated February 2009. The MCE was determined in Section 2.6.6 of the report to have a maximum ground acceleration of 0.09 g.

3.11.5 Stability Analysis Results

The factors of safety for the embankments are provided in Table 3.11-3. The table provides results for three methods of analysis, namely:

- Bishop method
- Janbu method
- Morgenstern-Price method

The analyses shown in Table 3.11-3 below indicate that the outer slopes of the ponds have a minimum factor of safety of approximately 2.51 under normal static loading conditions assuming that the HDPE liners remain intact, preventing a phreatic surface from developing in the embankment. The minimum factor of safety reduces to approximately 1.79 during the MCE seismic event.

Should the HDPE liner fail, a drain installed in the embankment will help to lower the phreatic surface and prevent the downstream toe from becoming saturated. The factors of safety do reduce, with the minimum factor of safety under normal static loading conditions reducing to approximately 1.67. Under MCE seismic loading conditions the minimum factor of safety reduces to approximately 1.15.

The inner slope is less critical in terms of preventing a breach of the embankment, but was evaluated for stability assuming the HDPE liners remain intact. The minimum factor of safety under normal static loading conditions was calculated to be 1.90, while under MCE seismic loading conditions this reduces to approximately 1.47.

The factors of safety indicate that both the inner and outer the slopes are stable under both static and MCE seismic loading conditions.

Table 3.11-3 – Stability Analysis Factors of Safety

Pond	Description	Analysis	Factor of Safety		
			Bishop	Janbu	Morgenstern-Price
Dewey Radium Settling Pond	Outer slope – assuming intact HDPE liner	Static	2.87	2.63	2.87
		Seismic (MCE)	2.04	1.89	2.04
	Outer slope – assuming HDPE liner has failed	Static	2.10	1.87	2.11
		Seismic (MCE)	1.44	1.29	1.45
	Inner slope – assuming intact HDPE liner	Static	2.03	1.91	2.03
		Seismic (MCE)	1.56	1.47	1.56
Dewey Outlet Pond	Outer slope – assuming intact HDPE liner	Static	3.00	2.76	3.00
		Seismic (MCE)	2.14	1.98	2.14
	Outer slope – assuming HDPE liner has failed	Static	2.23	1.95	2.23
		Seismic (MCE)	1.51	1.35	1.52
	Inner slope – assuming intact HDPE liner	Static	2.99	2.79	2.99
		Seismic (MCE)	2.13	1.99	2.13
Dewey Storage Ponds	Outer slope – assuming intact HDPE liner	Static	2.68	2.51	2.68
		Seismic (MCE)	1.91	1.79	1.91
	Outer slope – assuming HDPE liner has failed	Static	1.97	1.74	1.98
		Seismic (MCE)	1.36	1.22	1.37
	Inner slope – assuming intact HDPE liner	Static	2.58	2.43	2.58
		Seismic (MCE)	1.83	1.73	1.83
Burdock Radium Settling/Spare Ponds	Outer slope – assuming intact HDPE liner	Static	2.93	2.74	2.93
		Seismic (MCE)	2.08	1.96	2.09
	Outer slope – assuming HDPE liner has failed	Static	2.03	1.80	2.04
		Seismic (MCE)	1.40	1.25	1.41
	Inner slope – assuming intact HDPE liner	Static	2.12	1.98	2.12
		Seismic (MCE)	1.63	1.53	1.63
Burdock Outlet Pond	Outer slope – assuming intact HDPE liner	Static	2.93	2.76	2.93
		Seismic (MCE)	2.09	1.97	2.10
	Outer slope – assuming HDPE liner has failed	Static	2.01	1.80	2.02
		Seismic (MCE)	1.38	1.24	1.40
	Inner slope – assuming intact HDPE liner	Static	3.14	2.92	3.14
		Seismic (MCE)	2.24	2.09	2.24
Burdock Storage Ponds	Outer slope – assuming intact HDPE liner	Static	2.75	2.60	2.75
		Seismic (MCE)	1.94	1.84	1.95
	Outer slope – assuming HDPE liner has failed	Static	1.87	1.67	1.87
		Seismic (MCE)	1.28	1.15	1.29
	Inner slope – assuming intact HDPE liner	Static	2.46	2.33	2.46
		Seismic (MCE)	1.81	1.72	1.82

Table 3.11-3 – Stability Analysis Factors of Safety

Pond	Description	Analysis	Factor of Safety		
			Bishop	Janbu	Morgenstern-Price
Central Plant Pond (Burdock)	Outer slope – assuming intact HDPE liner	Static	3.04	2.86	3.04
		Seismic (MCE)	2.16	2.02	2.16
	Outer slope – assuming HDPE liner has failed	Static	2.09	1.86	2.10
		Seismic (MCE)	1.45	1.29	1.46
	Inner slope – assuming intact HDPE liner	Static	2.03	1.90	2.03
		Seismic (MCE)	1.59	1.48	1.59

3.12 Embankment Settlement

Elastic theory was used to obtain an estimate of embankment settlements using material characteristics derived from the triaxial test results. Assuming a maximum embankment height of 30 ft, elastic theory predicts that the elastic settlement of an embankment having a crest width of 40 ft and 1(v):4.5(h) side slopes is likely to be less than 1 ft. This settlement will occur during construction, and will be accommodated by placing fill to ensure that final design crest elevations are achieved. Due to the relatively low embankments that are being constructed, settlement due to consolidation is not expected to be significant.

3.13 Summary of Pond Characteristics

Table 3.13-1 summarizes the pond characteristics at the Dewey-Burdock Uranium Project.

Table 3.13-1 – Pond Characteristics and Design Features

Parameter	Radium Settling/Spare Ponds	Central Plant Pond	Outlet Ponds	Storage and Spare Storage Ponds
Number of Ponds:				
Dewey	1 Radium Settling 1 Spare	-	1	4 Storage 1 Spare Storage
Burdock	1 Radium Settling 1 Spare	1	1	4 Storage 1 Spare Storage
Active Storage (per pond):				
Process water and stormwater from land application areas	39.4*	35.0	2.8	61.8
Stormwater falling on ponds	0**	1.2	2.1	2.0
Total	**39.4**	**36.2**	**4.9**	**63.8**
Crest width	220 ft	465 ft	162 ft	362 ft
Crest length	880 ft	465 ft	280 ft	362 ft
Depth	Varies 10.0 to 25.5 ft	Varies: 18.4 to 25.0 ft	Varies 12.3 to 14.0 ft	Varies 27.1 to 30.0 ft
Freeboard	3 ft	3 ft	3 ft	3 ft
Upstream embankment slope	3H:1V	3H:1V	4.5H:1V	4.5H:1V
Downstream embankment slope	4.5H:1V	4.5H:1V	4.5H:1V	4.5H:1V
Exterior embankment crest width	40 ft	40 ft	40 ft	40 ft
Interior embankment crest width	30 ft	N/A	30 ft	30 ft
Bottom grade	2 percent - graded towards leak detection sump		1 percent - graded towards a corner	
Lining system	Prepared subgrade or compacted random fill 1-ft-thick soil liner compacted to 95 percent standard proctor density 60-mil-smooth HDPE bottom (secondary) geomembrane 80-mil-textured HDPE top (primary) geomembrane Leak detection system consisting of geonet placed between primary and secondary geomembranes Leak detection sump and access port system 3-ft-deep by 3-ft-wide geomembrane anchor trench		Prepared subgrade or compacted random fill 1-foot-thick soil liner compacted to 95 percent standard proctor density 40-mil-textured HDPE geomembrane 3-ft-deep by 3-ft-wide geomembrane anchor trench	

*Includes 0.2-acre-ft storage for sludge

**Stormwater from the radium settling pond overflows into the outlet pond where it is stored

4.0 Deep Well Disposal Pond Design

4.1 Design Flows

Three water streams resulting from mining activities report to the ponds:

- Bleed water from the production wells
- Restoration water from the restoration wells
- Brine from the CPP

Bleed and restoration water is pumped to the radium settling ponds, where it is treated and used for deep well disposal. Some water from the CPP will be pumped to the CENTRAL PLANT pond where it will be stored. Allowance has been made for all ponds to store water resulting from the 100-year, 24-hour storm event while maintaining 3 ft of freeboard.

4.1.1 Production Well Bleed Water

The in situ leach process includes for up to 3 percent of the water pumped from the production wells to be bled from the system. Total production water is approximately 4,000 gpm, resulting in a bleed flow of approximately 120 gpm.

4.1.2 Wellfield Restoration Water

This water, having a flow rate of approximately 500 gpm, will be used to flush the mineralized target zone following uranium recovery. Once it returns to the surface, 120 gpm of this will be pumped to the radium settling ponds for treatment and deep well disposal, with the remainder being recycled as restoration water.

4.1.3 Brine from the Central Processing (Burdock) Plant Site

This water, having a flow rate of approximately 12 gpm, will be produced as part of the uranium extraction process.

4.1.4 Precipitation

Water falling directly on the pond surfaces will be stored in the ponds and either used for restoration water or deep well disposal.

4.2 Pond Design Requirements

Active storage requirements for the radium settling, outlet, surge and central plant ponds are provided below. In addition to active storage requirements, all ponds will be provided with 3 ft of freeboard. The catchment areas of the ponds will be minimized by grading all roads away from them, and by providing stormwater diversions to prevent water from upstream catchments from reporting to them.

Figure 4.2-1 provides the Dewey Plant Site Plan, and Figure 4.2-2 includes the pond cross sections.

Figure 4.2-3 provides the Burdock Plant Site Plan, and Figure 4.2-4 includes the pond cross sections.

4.2.1 Radium Settling Ponds

Radium is settled out of solution by adding barium chloride to the water. Co-precipitation of radium occurs when natural sulfate (SO_4) in the water combines with radium (Ra) and barium (Ba) to form $RaBaSO_4$. The requirements for efficient settlement of solids out of a solution include have been incorporated into the design of the ponds and include the following:

- Sufficient retention time for the settlement of radium out of solution
- Providing adequate surface area to prevent the development of large surface currents
- Providing a pond geometry or arrangement that will prevent short circuiting of flows through the pond

Radium is settled out of solution by adding barium chloride to the water. Co-precipitation of radium occurs when natural sulfate (SO_4) in the water combines with radium (Ra) and barium (Ba) to form $RaBaSO_4$. All discussions in the following sections, therefore, refer to the settlement of radium barium sulfate.

4.2.1.1 Retention Time and Storage

Water in the ponds must be retained for sufficient length of time to allow barium radium sulfate to settle out of solution. A literature survey of radium settling ponds indicated that typical retention times range from eight to 14 days. A retention time of 14 days has been adopted for this project. For a flow rate of 252 gpm, this requires that the pond have a minimum storage volume of 15.6-acre-ft. In addition, the ponds are expected to accumulate 321 ft^3/year of radium barium sulfate sludge. For a 10-year project life, this will amount to 0.074-acre-ft of storage. The design allows identical radium settling ponds to be constructed at the Dewey and Burdock Sites, capable of storing 15.9-acre-ft each, allocated as follows:

- 15.8-acre-ft for bleed and restoration water
- 0.1-acre-ft for sludge accumulation

Stormwater will overflow into the outlet pond, which has been designed to accommodate the 100-year, 24-hour storm event for both itself and the radium settling pond.

4.2.1.2 Surface Area

To promote settling, the pond surface area should be large enough to prevent significant surface currents from developing. Should these develop, they could keep the radium barium sulfate in suspension. They could also result in short circuiting, with water flowing directly from the pond inlet to the outlet.

The literature survey indicated that a minimum area of approximately 0.6 acre should be allowed for every 100 gpm of flow. For a flow of 252 gpm, this results in area of 1.51 acres. The radium settling pond has been designed to have a water surface area of 2.20 acres.

4.2.1.3 Pond Geometry

Unless baffles are provided, the length of a settling pond should ideally be at least 4 times its width. To meet this criterion, the radium settling pond has been designed to have a crest length of 680 ft and a crest width of 170 ft.

4.2.2 Outlet Ponds

Identical outlet ponds have been designed for the Dewey and Burdock Sites. They have been designed to accommodate approximately three day's production water, equating to 3.3-acre-ft, and precipitation from the 100-year, 24-hour storm event falling on both the radium settling and outlet ponds. The ponds have been designed to store the following:

- 3.4-acre-ft for treated water for deep well injection
- 1.2-acre-ft for the 100-year, 24-hour design storm event falling on the radium settling pond
- 0.5-acre-ft for the 100-year, 24-hour design storm event falling on the outlet pond

4.2.3 Surge Ponds

Identical surge ponds have been designed for the Dewey and Burdock Sites. They serve as a volume buffer for water flowing out of the radium settling ponds and have been sized to accommodate seven day's production water. They have been designed to have a total storage of 8.4-acre-ft, allocated as follows:

- 7.8-acre-ft for treated water for deep well injection
- 0.6-acre-ft for the 100-year, 24-hour design storm event falling on the pond surface

4.2.4 Central Plant Pond

The central plant pond is located at the Burdock Site, and is provided to store brine from the plant. The central plant pond has been designed to have the same active storage as the spare pond, and has a total storage of 15.9-acre-ft, allocated as follows:

- 15.2-acre-ft brine
- 0.7-acre-ft for the 100-year, 24-hour design storm event falling on the pond surface

4.2.5 Spare Pond

The spare ponds have been designed to be identical to the radium settling ponds, which are the largest ponds in the system. The spare ponds are located adjacent to the radium settling ponds, and have been designed to accommodate water from any of the other ponds should their liners fail.

4.3 Water Flow Configurations

Water will be routed through the radium settling ponds to maximize retention time and facilitate the settlement of barium sulfate. Figure 4.3-1 provides the Dewey Plant Site Flow Diagram and Figure 4.3-2 provides the Burdock Plant Site Flow Diagram.

4.4 Pond Lining Systems

The lining system for the radium settling, spare and central plant ponds will consist of the following:

- An 80-mil-textured primary HDPE liner.
- A 60-mil-smooth secondary HDPE liner.

- A 12-inch-thick compacted clay liner, having a maximum permeability of $1x10^{-7}$ cm/sec. This liner will be constructed below the secondary HDPE liner.
- A geonet sandwiched between the primary and secondary HDPE liners.

The outlet and surge ponds will contain treated water that will be used for deep well injection. The liner requirement on those ponds is therefore less stringent, and will consist of the following:

- An 40-mil-textured HDPE liner.
- A 12-inch-thick compacted clay liner, having a maximum permeability of $1x10^{-7}$ cm/sec. This liner will be constructed below the HDPE liner.

4.5 Leak Detection Systems

The radium settling, spare and central plant ponds will include a geonet drainage layer installed between the primary and secondary HDPE liners. The geonet will drain into a leak detection sump. A minimum grade of 2 percent will be maintained across the bottom of the ponds to facilitate the drainage of water into the leak detection sump should a leak develop. A leak detection access port and pump will be provided at the sump to allow any water collecting there to be pumped out and monitored. Pipes feeding into the double-lined ponds will be dual contained, with the carrier and containment pipes being connected to the primary and secondary HDPE liners, respectively. The leak detection system is shown on Figure 4.5-1.

4.6 Foundation Preparation

Foundation preparation on all ponds will include the following:

- Removing vegetation, existing structures and unsuitable foundation materials
- Subgrade preparation
- Site grading

More detail on the items listed above is provided in Table 4.6-1.

Table 4.6-1 – Foundation Preparation Requirements

Item	Description
Vegetation	Clear and grub vegetation
Structures	Remove any existing structures
Surface soils	- Strip organic soil matter for a minimum of 10 ft beyond the pond embankment limits - Place the stripped soil in temporary stockpiles for final reclamation - Stockpiles should be located as close to the stripped areas as possible - Proposed stockpile locations are indicated on Figures 4.6-1, 4.2-1, and 4.2-3
	Scarify, moisture condition and compact the top 6 inches of the stripped ground surface in fill areas to a minimum of 90 percent of the maximum Modified Proctor Dry Density (ASTM D 1557)
Site Grading	Undertake site grading cut and fill. Compact graded materials to a minimum of 90 percent of the maximum dry density (ASTM D 1557) within ± 2 percent of the optimum moisture content

4.7 Embankment Drainage

An embankment drainage system will be installed in the outer face of all embankments to prevent the outer toe of the embankment from becoming saturated should a HDPE liner system fail. Water collected by the drain system will be conveyed to a sump, from where it will be pumped back to the ponds.

4.8 Pond Seepage Analyses

Seepage analyses were undertaken for the outer embankments of the ponds to model the phreatic surface through the outer embankments of the ponds should the HDPE liners fail. The phreatic surface determined from the seepage analysis was then used to model embankment slope stability for that condition.

All ponds will be HDPE lined, with the HDPE liner being underlain by a 1-ft-thick clay liner. Negligible seepage is expected from them under normal operating conditions.

4.8.1 Material Properties

Flexible wall permeability tests are summarized in Table 3.10-1. The median undisturbed permeabilities have been assumed for the in situ soils, while the median remolded permeabilities have been assumed for the embankments. In addition, regulatory requirements specify that a 1-ft-thick clay liner having a maximum permeability of $1\text{x}10^{-7}$ be used below the HDPE liners in the ponds. Material from the pond excavation will be selected to meet this criterion. If necessary, borrow areas will be developed to source this material.

Sand used in the embankment drainage system was assumed to have a permeability of $5x10^{-4}$ cm/sec.

4.8.2 Analysis

For the seepage analysis, it was assumed that the HDPE liners in the ponds fail completely, with the 1-ft-thick clay liner providing the only barrier to seepage through the embankment. The seepage analysis was completed using the GeoStudio 2007 software package.

4.9 Pond Stability Analyses

Stability analyses on the pond embankments were completed using the GeoStudio 2007 software package. The sections selected for the analysis are located at the highest points of the embankments.

4.9.1 Analyses

The following analyses were conducted on each of the ponds:

- A static stability analysis, assuming that the liners are intact (no phreatic surface in the embankment)
- A pseudostatic analysis, assuming the liners are intact and modeling the MCE acceleration
- A static analysis assuming that the liners have completely failed, allowing a phreatic surface to develop in the embankment
- A pseudostatic analysis assuming that the liners have completely failed, allowing a phreatic surface to develop in the embankment, and modeling the MCE acceleration

4.9.2 Soil Strengths

Soil strengths were obtained from three tri-axial tests that were conducted on material samples collected during the site investigation, and are presented in Table 3.11-1.

The material strength values obtained from test pit TP 02-7 were used for the analyses undertaken on the ponds at the Dewey Site.

4.9.3 Material Densities

In situ material densities were obtained from undisturbed samples collected during the site investigation. The densities of embankment materials were obtained from compaction tests undertaken on samples collected from site, and are summarized in Table 3.11-2.

Median undisturbed densities have been assumed for in situ soils, while the median densities from the compaction tests have been assumed for the embankments and clay liners.

4.9.4 Seismic Ground Acceleration Values

MCE ground accelerations were obtained from the document "Dewey-Burdock Project, Application for NRC Uranium Recovery License, Fall River and Custer Counties, South Dakota, Technical Report" dated February 2009. The MCE was determined in Section 2.6.6 of the report to have a maximum ground acceleration of 0.09 g.

4.9.5 Stability Analysis Results

The factors of safety for the embankments are provided in Table 4.9-1. The table provides results for three methods of analysis, namely:

- Bishop method
- Janbu method
- Morgenstern-Price method

Table 4.9-1 – Stability Analysis Factors of Safety

Pond	Description	Analysis	Factor of Safety		
			Bishop	Janbu	Morgenstern-Price
Dewey Radium Settling/Spare Ponds	Outer slope – assuming intact HDPE liner	Static	3.00	2.76	3.00
		Seismic (MCE)	2.14	1.97	2.14
	Outer slope – assuming HDPE liner has failed	Static	2.22	1.97	2.23
		Seismic (MCE)	1.52	1.36	1.53

Table 4.9-1 – Stability Analysis Factors of Safety

Pond	Description	Analysis	Factor of Safety		
			Bishop	**Janbu**	**Morgenstern-Price**
Central Plant Pond (Burdock)	Outer slope – assuming intact HDPE liner	Static	3.10	2.88	3.10
		Seismic (MCE)	2.21	2.06	2.21
	Outer slope – assuming HDPE liner has failed	Static	2.22	1.96	2.22
		Seismic (MCE)	1.52	1.36	1.53
	Inner slope – assuming intact HDPE liner	Static	2.19	2.03	2.19
		Seismic (MCE)	1.70	1.58	1.70

The above analyses indicate that the outer slopes of the ponds have a minimum factor of safety of approximately 2.66 under normal static loading conditions assuming that the HDPE liners remain intact, preventing a phreatic surface from developing in the embankment. The minimum factor of safety reduces to approximately 1.90 during the MCE seismic event.

Should the HDPE liner fail, a drain installed in the embankment will help to lower the phreatic surface and prevent the downstream toe from becoming saturated. The factors of safety do reduce, with the minimum factor of safety under normal static loading conditions reducing to approximately 1.84. Under MCE seismic loading conditions the minimum factor of safety reduces to approximately 1.28.

The inner slope is less critical in terms of preventing a breach of the embankment, but was evaluated for stability assuming the HDPE liners remain intact. The minimum factor of safety under normal static loading conditions was calculated to be 2.03, while under MCE seismic loading conditions this reduces to approximately 1.58.

The above factors of safety indicate that the slopes are stable under both static and MCE seismic loading conditions.

4.9.6 Embankment Settlement

Elastic theory was used to obtain an estimate of embankment settlements using material characteristics derived from the triaxial test results. Assuming a maximum embankment height of 30 ft, elastic theory predicts that the elastic settlement of an embankment having a crest width of 40 feet and 1(v):4.5(h) side slopes is likely to be less than 1 ft. This settlement will occur during construction, and will be accommodated by placing fill to ensure that final design crest elevations are achieved. Due to the relatively low embankments that are being constructed, settlement due to consolidation is not expected to be significant.

4.9.7 Summary of Pond Characteristics

Table 4.9-2 summarizes the pond characteristics at the Dewey-Burdock Project.

Table 4.9-2 – Pond Characteristics and Design Features

Parameter	Radium Settling/Spare Ponds	Central Plant Pond	Outlet Ponds	Surge Ponds
Number of Ponds:				
Dewey	1 Radium Settling 1 Spare	-	1	1
Burdock	1 Radium Settling 1 Spare	1	1	1
Active Storage (per pond):				
Process water and stormwater from land application areas	15.9*	15.2	3.4	7.8
Stormwater falling on ponds	0**	0.7	1.7	0.6
Total	**15.9**	**15.9**	**5.1**	**8.4**
Crest width	170	275	160	250
Crest length	680	275	370	250
Depth	Varies 7.5 to 19.5 ft	Varies: 15.8 to 20.5 ft	Varies 11.4 to 14.0 ft	Varies 15.0 to 16.5 ft
Freeboard	3 ft	3 ft	3 ft	3 ft
Upstream embankment slope	3H:1V	3H:1V	4.5H:1V	4.5H:1V
Downstream embankment slope	4.5H:1V	4.5H:1V	4.5H:1V	4.5H:1V
Exterior embankment crest width	40 ft	40 ft	40 ft	40 ft
Interior embankment crest width	30 ft	N/A	30 ft	N/A
Bottom grade	2 percent - graded towards leak detection sump		1 percent - graded towards a corner	
Lining system	Prepared subgrade or compacted random fill 1-foot-thick soil liner compacted to 95 percent standard proctor density 60-mil-smooth HDPE bottom (secondary) geomembrane 80-mil-textured HDPE top (primary) geomembrane Leak detection system consisting of geonet placed between primary and secondary geomembranes Leak detection sump and access port system 3-ft-deep by 3-ft-wide geomembrane anchor trench		Prepared subgrade or compacted random fill 1-foot-thick soil liner compacted to 95 percent standard proctor density 40-mil-textured HDPE geomembrane 3-ft-deep by 3-ft-wide geomembrane anchor trench	

*Includes 0.1 acre-ft storage for sludge

**Stormwater from the radium settling pond overflows into the outlet pond where it is stored

Appendix A

Regulatory Requirements

A-1 USNRC Regulatory Requirements
A-2 South Dakota DENR Regulatory Requirements

Knight Piésold
CONSULTING

Appendix A-1

USNRC Regulatory Requirements

The USNRC regulatory requirements relating to surface impoundments are contained in NRC Regulations 10 CFR Part 40 Appendix A, Criterion 5A, Regulatory Guide 3.11 and NUREG-1569. These are summarized below:

- The liner must be designed, constructed and installed to prevent any migration of wastes out of the impoundment to the adjacent subsurface soil, groundwater or surface water during its life.
- Closure must make allowance for the removal of or decontamination of any of all waste residues, contaminated containment system components, contaminated subsoils, and structures and equipment contaminated with waste and leachate.
- For impoundments that will be closed with the liner material left in place, the liner must be constructed from materials that prevent wastes from migrating into them during the active life of the facility.
- Liners must be constructed from materials that have appropriate chemical properties and sufficient strength and thickness to prevent failure due to:
    - Pressure gradients
    - Physical contact with the waste or leachate to which they are exposed
    - Climatic conditions
    - Stress of installation
    - Stress of daily operation
- Liners must be placed on a foundation or base capable of providing support to the liner and resistance to pressure gradients above and below the liner. This must prevent failure due to settlement, compression or uplift.
- Liners must be installed to cover all surrounding earth that would otherwise be likely to be in contact with the wastes or leachate.
- Dykes forming any surface impoundment must be designed, constructed and maintained with sufficient structural integrity to prevent massive failure of the dykes. In ensuring the structural integrity, it must not be assumed that the liner system will not function without leakage during the active life of the impoundment.
- A leak detection system must be installed below synthetic liners to ensure that major failures are detected if they occur.

- Where clay liners are used, or where relatively thin in situ clay soils are to be relied upon for seepage controls, tests must be conducted to confirm that no significant deterioration of permeability or stability properties will occur with continuous exposure of the clay to tailings solutions. Tests must be run for a sufficient period of time to reveal any effects if they are going to occur.

- The design, installation and operation of surface impoundments must have sufficient capacity that the entire contents of one impoundment can be transferred to another surface impoundment in case of a leak.

- Surface impoundments must be designed, constructed, maintained and operated to prevent overtopping from normal or abnormal operations, equipment malfunctions and human error.

- Stability analyses of slopes including seismic stability, settlement and seepage analyses.

- Basic design criteria for stability of the retention system and minimum factors of safety.

Knight Piésold
CONSULTING

Appendix A-2

South Dakota DENR Regulatory Requirements

The South Dakota DENR regulatory requirements relating to surface water ponds are contained in the South Dakota Legislature Administrative Rules 74:29:11:23 In Situ Leach Mining: Pond and Surface Impoundment Design and Construction Requirements. These are summarized below:

- General design and construction requirements include:
  - A geotechnical and stability analysis to determine the suitability of the site and materials for construction
  - A minimum of 3-feet of freeboard
  - Maximum side slopes of 3 horizontal to 1 vertical
  - A minimum bottom slope of 2 percent
  - Provisions for migratory bird and wildlife protection
  - A minimum capacity of normal operating levels plus storage for the 100-year, 24-hour storm event
- A double liner must be included for impoundments that are to contain fluids that have the potential to pollute surface or ground water. The liner system must conform to the following:
  - The liners shall be separated by a leak detection, collection and recovery system. At a minimum, this must consist of:
    1. A design that will rapidly remove fluids to minimize hydraulic head on the secondary liner.
    2. A drain layer of clean sand or gravel, or a geonet drainage product. The system shall be constructed of materials chemically resistant to the fluids contained in the pond or impoundment.
    3. The system shall have a minimum hydraulic conductivity of 0.01 cm/sec.
    4. The drain layer shall cover the entire pond or impoundment if possible. At a minimum, it must cover the pond or impoundment to the high water mark.

5. The system shall be capable of draining the fluids to a collection gallery for recovery. If the collection gallery is not free draining, it shall be continuously pumped to minimize hydraulic head on the secondary liner.

6. The permit application must include a leakage response plan detailing actions that will be taken in response to the detection of liner system leakage including notification, reporting, monitoring and repair.

- The bottom liner shall be composite liner, consisting of one of the following:

1. An upper geomembrane liner and a lower compacted soil liner, having the following requirements:

   a. The soil liner shall have a compacted maximum coefficient of permeability of $1x10^{-7}$ cm/sec.

   b. The soil liner shall have a one-foot thick compacted thickness placed in 6-inch scarified and compacted lifts, with no materials greater than three inches in diameter.

   c. The soil liner shall meet compaction specifications equivalent to 95 percent standard proctor density with a moisture content of 0 to 6 percent of optimum moisture.

   d. The geomembrane and soil liner shall be in direct contact, with minimal void spaces, to minimize lateral flow of liquids at the geomembrane/soil liner interface.

2. A geosynthetic clay liner, having the following requirements:

   a. For bentonite clay encapsulated by geotextile layers, the geosynthetic clay liner shall be overlain by a geosynthetic liner. The geosynthetic liner shall have a minimum 60-mil thickness.

   b. For bentonite clay bonded to a geomembrane liner, the geomembrane liner shall have a minimum 60-mil thickness. During installation, the geomembrane shall be the upper layer of the composite liner.

c. Installation of the geosynthetic clay liners must be consistent with the manufacturer's specifications and recommendations.

- Liners systems must be constructed of materials that have the strength, thickness and chemical properties needed to prevent failure due to:

1. Pressure gradients
2. Physical contact with the waste or fluids to which they are exposed
3. Climatic conditions
4. Stress of installation
5. Stress of daily operation

- Liner design and construction requirements include at a minimum:

1. The primary (uppermost) liner shall have an 80 mil thickness, and the secondary (bottom) geomembrane shall have a 60 mil thickness.
2. The liners shall be compatible with the fluids to be contained.
3. Liners shall have a life expectancy longer than the life of the facility.
4. Installation of the liners must be consistent with the manufacturer's specifications and recommendations.

0.0	42.8	9.5	33.3	33.3	
25.0	37.3	15.1	22.2	22.2	7.5E-06
9.0	35.9	16.5	19.4	19.4	6.9E-06
11.0	34.3	18.0	16.3	16.3	7.3E-06
6.0	33.7	18.7	15.0	15.0	6.4E-06
18.0	31.9	20.5	11.4	11.4	7.0E-06
			Avg.of Last 4 Rdgs.		**7.0E-06**
			Max.Hyd.Gradient:	3.8	

General Test Notes:
1) Tap water was used as the permeant.
2) Back pressure saturation continued until 'B' parameter a minimum of 0.95.
3) Target remolding parameters: 104.7 pcf @ 14.6% moisture.

FLEXIBLE WALL PERMEABILITY TEST
ASTM D 5084-03
Falling Head / Increasing Tailwater Pressure

Type of Test:
CU with Pore Pressures

Sample Type: Remolded, 95%MDD @ OMC

Description: lean clay with sand

LL= 43 **PL=** 11 **PI=** 32

Specific Gravity= 2.72

Remarks: Failure tangents drawn at approximately 15% strain.

Parameters for Specimen No. 2

Specimen Parameter	Initial	Saturated	Consolidated	Final
Moisture content: Moist soil+tare, gms.	715.600			880.700
Moisture content: Dry soil+tare, gms.	607.000			725.000
Moisture content: Tare, gms.	0.000			118.000
Moisture, %	17.9	24.5	25.7	25.7
Moist specimen weight, gms.	715.6			
Diameter, in.	2.43	2.43	2.44	
Area, in.²	4.63	4.63	4.69	
Height, in.	4.90	4.90	4.93	
Net decrease in height, in.		0.00	-0.03	
Wet Density, pcf	120.2	126.9	125.6	
Dry density, pcf	101.9	101.9	100.0	
Void ratio	0.6660	0.6660	0.6987	
Saturation, %	73.1	100.0	100.0	

Test Readings for Specimen No. 2

Membrane modulus = 0.124105 kN/cm²

Membrane thickness = 0.064 cm

Consolidation cell pressure = 55.00 psi (7.92 ksf)

Consolidation back pressure = 40.00 psi (5.76 ksf)

Consolidation effective confining stress = 2.16 ksf

Strain rate, %/min. = 0.03

Fail. Stress = 1.35 ksf **at reading no.** 80

Parameters for Specimen No. 3

Specimen Parameter	Initial	Saturated	Consolidated	Final
Moisture content: Moist soil+tare, gms.	714.700			863.000
Moisture content: Dry soil+tare, gms.	607.000			725.400
Moisture content: Tare, gms.	0.000			118.400
Moisture, %	17.7	24.6	23.2	22.7
Moist specimen weight, gms.	714.7			
Diameter, in.	2.43	2.43	2.41	
Area, in.²	4.64	4.64	4.57	
Height, in.	4.90	4.90	4.86	
Net decrease in height, in.		0.00	0.04	
Wet Density, pcf	119.8	126.8	128.3	
Dry density, pcf	101.8	101.8	104.2	
Void ratio	0.6687	0.6687	0.6301	
Saturation, %	72.2	100.0	100.0	

Test Readings for Specimen No. 3

Membrane modulus = 0.124105 kN/cm²

Membrane thickness = 0.064 cm

Consolidation cell pressure = 70.00 psi (10.08 ksf)

Consolidation back pressure = 40.00 psi (5.76 ksf)

Consolidation effective confining stress = 4.32 ksf

Strain rate, %/min. = 0.03

Fail. Stress = 2.70 ksf **at reading no.** 86

Type of Test:
CU with Pore Pressures

Sample Type: Remolded, 95%MDD @ OMC

Description: sandy lean clay

LL= 21 **PL=** 12 **PI=** 9

Specific Gravity= 2.72

Remarks: Failure tangents drawn at approximately 6% strain.

Fig. _______

Client:

Project: Powertech

Location: TP08

Depth: 6'

Proj. No.: DV102-279.02 **Date Sampled:** 7/21/08

TRIAXIAL COMPRESSION TEST

CU with Pore Pressures

Date: 7/21/08
Client:
Project: Powertech
Project No.: DV102-279.02
Location: TP08
Depth: 6'
Description: sandy lean clay
Remarks: Failure tangents drawn at approximately 6% strain.
Type of Sample: Remolded, 95%MDD @ OMC
Specific Gravity=2.72 **LL=**21 **PL=**12 **PI=**9
Test Method: COE uniform strain

Parameters for Specimen No. 1

Specimen Parameter	Initial	Saturated	Consolidated	Final
Moisture content: Moist soil+tare, gms.	747.800			905.900
Moisture content: Dry soil+tare, gms.	663.100			781.400
Moisture content: Tare, gms.	0.000			118.300
Moisture, %	12.8	19.7	19.0	18.8
Moist specimen weight, gms.	747.8			
Diameter, in.	2.42	2.42	2.41	
Area, in.^{2}	4.60	4.60	4.56	
Height, in.	4.97	4.97	4.95	
Net decrease in height, in.		0.00	0.02	
Wet Density, pcf	124.6	132.3	133.2	
Dry density, pcf	110.5	110.5	111.9	
Void ratio	0.5366	0.5366	0.5181	
Saturation, %	64.7	100.0	100.0	

Test Readings for Specimen No. 1

Membrane modulus = 0.124105 kN/cm^2
Membrane thickness = 0.064 cm
Consolidation cell pressure = 47.00 psi (6.77 ksf)
Consolidation back pressure = 40.00 psi (5.76 ksf)
Consolidation effective confining stress = 1.01 ksf
Strain rate, %/min. = 0.05
Fail. Stress = 0.96 ksf **at reading no.** 63

Type of Test:
CU with Pore Pressures

Sample Type: Remolded, 95%MDD @ OMC

Description: lean clay with sand

LL= 33 **PL=** 10 **PI=** 23

Specific Gravity= 2.72

Remarks: Failure tangents drawn at approximately 15% strain.

Parameters for Specimen No. 2

Specimen Parameter	Initial	Saturated	Consolidated	Final
Moisture content: Moist soil+tare, gms.	370.380			525.330
Moisture content: Dry soil+tare, gms.	314.360			463.040
Moisture content: Tare, gms.	0.000			148.680
Moisture, %	17.8	23.3	19.8	19.8
Moist specimen weight, gms.	370.4			
Diameter, in.	1.94	1.94	1.90	
Area, in.²	2.94	2.94	2.82	
Height, in.	3.92	3.92	3.84	
Net decrease in height, in.		0.00	0.08	
Wet Density, pcf	122.4	128.1	132.2	
Dry density, pcf	103.9	103.9	110.4	
Void ratio	0.6345	0.6345	0.5382	
Saturation, %	76.4	100.0	100.0	

Test Readings for Specimen No. 2

Membrane modulus = 0.124105 kN/cm²
Membrane thickness = 0.064 cm
Consolidation cell pressure = 55.00 psi (7.92 ksf)
Consolidation back pressure = 40.00 psi (5.76 ksf)
Consolidation effective confining stress = 2.16 ksf
Strain rate, %/min. = 0.05
Fail. Stress = 2.14 ksf **at reading no.** 80

Parameters for Specimen No. 3

Specimen Parameter	Initial	Saturated	Consolidated	Final
Moisture content: Moist soil+tare, gms.	369.700			492.150
Moisture content: Dry soil+tare, gms.	316.060			434.320
Moisture content: Tare, gms.	0.000			118.260
Moisture, %	17.0	23.8	18.0	18.3
Moist specimen weight, gms.	369.7			
Diameter, in.	1.93	1.93	1.87	
Area, in.²	2.93	2.93	2.73	
Height, in.	3.99	3.99	3.86	
Net decrease in height, in.		0.00	0.13	
Wet Density, pcf	120.7	127.7	134.6	
Dry density, pcf	103.2	103.2	114.1	
Void ratio	0.6462	0.6462	0.4888	
Saturation, %	71.4	100.0	100.0	

Test Readings for Specimen No. 3

Membrane modulus = 0.124105 kN/cm²

Membrane thickness = 0.064 cm

Consolidation cell pressure = 70.00 psi (10.08 ksf)

Consolidation back pressure = 40.00 psi (5.76 ksf)

Consolidation effective confining stress = 4.32 ksf

Strain rate, %/min. = 0.05

Fail. Stress = 2.88 ksf **at reading no.** 81

Appendix D

SPAW Model Results

Appendix D

SPAW Model Results

1.0 SPAW Model Results

1.1 Overview

This appendix describes the modeling that was used in the design of the land application system and associated settling ponds. Bleed water from the process lixiviant circuit will be extracted following uranium removal in the ion-exchange (IX) columns. Bleed water will then flow through secondary IX columns to further remove uranium and other metals. This water will be discharged to lined settling ponds, where radium will be precipitated using barium sulfate. Water from these ponds will then be pumped to center pivot sprinklers and used to irrigate alfalfa or other suitable crops from March 29 to October 31 during each year of operation. Water from the ponds will be sampled before it is pumped to the sprinklers to ensure that it meets the applicable discharge standards for all constituents.

It is anticipated that several potential crops such as alfalfa, corn, sorghum and several species of salt tolerant wheatgrass could be irrigated. During the irrigation season, water application rates will be determined during operation to optimize both evaporation and crop production.

The design of the land application system was developed based on modeling using the SPAW model, which is described in the following sections. Two land application areas, one at the Dewey site and one at the Burdock site will be used. The total irrigated area at any given time at the Dewey site would be 315 acres, consisting of four 50-acre pivots, four 25-acre pivots, plus one 15-acre pivot. In addition, there would be one 50-acre pivot and one 15-acre pivot on standby (total pivots at Dewey is five 50-acre pivots, four 25-acre pivots, and two 15-acre pivots). Pumping at Dewey would occur for 24 hours every day from March 29 to May 10 at a rate of 297 gallons per minute (gpm); from May 11 to September 24 at a rate of 653 gallons per minute; and from September 25 to October 31 at a rate of 297 gallons per minute.

The total irrigated area at any given time at the Burdock site would also be 315 acres (six 50-acre pivots plus one 15-acre pivot). In addition, there would be two 25-acre pivots and one 15-acre pivot on standby. The total pivots at Burdock would be six 50-acre pivots, two 25-acre pivots, and two 15-acre pivots. Pumping at Burdock would also occur for 24 hours on every day from

March 29 to May 10 at 297 gallons per minute; from May 11 to September 24 at a rate of 653 gallons per minute; and from September 25 to October 31 at a rate of 297 gallons per minute.

Five single-lined impoundments (ponds) will be constructed at the Dewey site for the temporary storage of the irrigation water. Each pond will be 465 feet x 465 x 30 feet deep including 3 feet of freeboard, with an operating capacity of 61.8 acre-feet. Four of the ponds will be operational at any given time, with the remaining pond serving as a backup. In addition to the storage ponds, a double-lined radium settling pond with leak detection and a single-lined outlet pond will also be constructed at Dewey. The radium settling pond will be 880 feet x 200 feet x 22.5 feet deep, including 3 feet of freeboard, and will have an operational storage of 39.4 acre-ft. The outlet pond will be 280 feet x 162 feet x 14 feet deep including 3 feet of freeboard, and will have an operational storage of 4.9 acre-ft.

Four single-lined impoundments (ponds) will be constructed at the Burdock site for the temporary storage of the irrigation water. Each pond will be 465 feet x 465 feet x 30 feet deep including 3 feet of freeboard, with an operating capacity of 61.8 acre-feet. In addition to the storage ponds, double-lined radium settling, spare and central processing plant (CPP) ponds with leak detection, and a single-lined outlet pond will also be constructed at Burdock. The radium settling and spare ponds will be 880 feet x 200 feet x 25.5 feet deep, including 3 feet of freeboard, and will have an operational storage of 39.4 acre-ft. The CPP pond will be 362 feet x 362 feet x 25 feet including 3 feet of freeboard, and will have an operational storage capacity of 36.2 acre-feet. The outlet pond will be 280 feet x 162 feet x 14 feet deep including 3 feet of freeboard, and will have an operational storage of 4.9 acre-ft.

1.2 SPAW Model Description

The SPAW (Soil-Plant-Air-Water) Model was developed by the U.S. Department of Agriculture (Saxton and Willey, 2006) to simulate the daily hydrologic water budgets of agricultural landscapes by two connected routines, one for farm fields and one for impoundments such as irrigation ponds. The field hydrology simulation is represented by: 1) daily climatic descriptions of precipitation, temperature, and evaporation, 2) a soil profile of interacting layers each with unique water holding characteristics, and 3) annual crop growth with management options for rotations, irrigation, and fertilization. The model output for the field hydrology routine includes a daily vertical, one-dimensional water budget depth for all major hydrologic processes such as runoff, infiltration, evapotranspiration, soil water profiles, and percolation.

Water volumes for each component of the water balance are estimated by multiplying the water budget depth times the associated field area.

Pond hydrology simulations provide water budgets by multiple input and depletion processes for impoundments whose water source is runoff from agricultural fields and/or water produced by wells or other sources. Model outputs for the pond hydrology routine include daily values of depth, volume, precipitation, evaporation, and change in storage for the period of simulation. The version of the SPAW model used was Version 6.02.75. The model has been extensively tested by the developers using research data and real-world applications.

1.2.1 Model Input Parameters

1.2.1.1 Meteorological Parameters

The local climate at the project site is continental, with hot summers, cold winters, and an average annual precipitation of 16.4 inches. The wettest months are from April to September. May and June are the months of highest average precipitation, with occasional thunderstorms that can be severe. Typical daytime temperatures range from 35 degrees Fahrenheit (^{o}F) in January to 85 ^{o}F in July, with nighttime temperatures dropping by approximately 15 to 30 ^{o}F.

Because of limited on-site climatic data, twenty-eight years of daily precipitation and temperature values (from 1980 to 2007) from the nearest available meteorological station at Edgemont, South Dakota were downloaded from the National Climatic Data Center and used as input data for the SPAW Model. The Edgemont station is approximately 13 miles southeast of the site at an elevation of 3460 feet above mean sea level (amsl). The project plant site is at 3720 feet amsl. Table 1.2-1 shows the average monthly air temperature data at the Edgemont station for the 28-year period of record.

Table 1.2-1: Average Monthly and Annual Air Temperature at Edgemont, SD Station (°F)

Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Annual
22.6	26.8	36.6	46.7	56.9	66.4	74.3	72.5	61.3	47.8	33.0	22.6	47.3

1.2.1.1.1 Precipitation

Daily precipitation values for the 28-year period of record from the Edgemont station were used as input data for the SPAW Model. Where daily data were absent in the record, the daily average for that month from the 28-yr record was used. No adjustments were made to the precipitation values for the 260-foot elevation difference between the Edgemont station and the project site. Table 1.2-2 shows the average monthly precipitation at the Edgemont station for the 28-yr period of record.

Table 1.2-2: Average Monthly and Annual Precipitation at Edgemont, SD Station (inches)

Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Annual
0.33	0.50	1.09	1.87	2.48	2.60	2.17	1.59	1.38	1.31	0.69	0.43	16.44

1.2.1.1.2 Potential Evapotranspiration

The SPAW model requires daily potential evapotranspiration (PET) data. Lake evaporation is a close estimate of PET, and is similar to PET values estimated using the Penman method. The mean annual lake evaporation (PET equivalent) at the site was determined to be 44 inches using the Evaporation Atlas for the Contiguous 48 United States (Farnsworth and Thompson, 1982). The monthly PET was calculated by applying the values for the monthly distribution of evaporation for the north central United States that are contained in the SPAW model. The daily PET for each month was then calculated by dividing the monthly PET by the number of days in the month. Table 1.2-3 shows the estimated average monthly and annual potential evapotranspiration at the site that was calculated using this method.

Table 1.2-3: Average Monthly and Annual Potential Evapotranspiration at Project Site (inches)

Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Annual
0.92	1.23	1.98	3.30	4.40	5.76	7.08	6.95	5.50	3.74	2.02	1.10	44.0

1.2.1.2 Material Properties

To characterize the soils at the site, eleven test pits were excavated on July 11 and 12, 2008. Samples were collected at various depths and analyzed for particle size distribution, dry bulk density, permeability, and other geotechnical parameters. Test pits 1 through 5 were excavated at the Dewey land application area, and test pits 6 through 11 were excavated at the Burdock land application area. Table 1.2-4 shows the USDA soil texture and dry bulk density for the test pit samples. These are the parameters that are used as input to the SPAW model.

Natural Resources Conservation Service (NRCS) soil survey maps for the land application area were downloaded from the NRCS Web Soil Survey. The particle size distributions for the

NRCS soil mapping units were compared to the laboratory particle size distributions for the test pit soil samples. This comparison showed that the laboratory results for the test pit samples generally fell within the range of particle size distributions for the NRCS survey soil mapping units.

1.2.2 Modeling Approach

The general assumptions for the SPAW model include the following:

1. The model is a one-dimensional vertical model.

2. The model assumes that the modeled area is spatially uniform in soil, crop and climate characteristics.

3. Model inputs and outputs are based on daily values.

4. The model does not does not include flow routing or channel descriptors.

5. Daily runoff is estimated as an equivalent depth over the simulation field by the USDA/SCS Curve Number method.

6. The field budget utilizes a one-dimensional vertical system beginning above the plant canopy and proceeding downward through the soil profile to a depth sufficient to represent the complete root penetration and subsurface hydrologic processes (lateral soil water flow is not simulated).

Specific assumptions related to this project are as follows:

1. Daily precipitation and temperature data used in the model are based on 28 years of record from the Edgemont, South Dakota station.

2. SPAW modeling was done for two land application and pond areas, the Dewey site and the Burdock site.

3. Soils data used in the modeling of the Dewey site was based on a composite of soils data from Test Pits 1, 2 and 5.

4. Soils data used in the modeling of the Burdock site was based on a composite of soils data from Test Pits 8, 9 and 10.

5. The 24/7 year-round inflow rate from process water and bleed water at each site is 310 gpm.

6. The irrigation season is from March 29 to October 31 each year (217 days).

7. Model runs were conducted assuming no crop (bare soil). This assumption ensures that the results will be conservative in terms of the resulting evapotranspiration and runoff, since it is difficult to model the response of alfalfa or other crops to the quality of the applied irrigation water and to the soil conditions present at the site.

8. The irrigation water will be applied at a rate that balances the total annual amount of process inflow water. The modeled application rate is 297 gpm from March 29 to May 10, 653 gpm from May 11 to September 24, and 297 gpm from September 25 to October 31.

9. Irrigation tailwater and rainfall runoff from the land application areas will be conveyed to collection areas at the edges of the land application areas and allowed to evaporate and seep into the soil.

10. The storage impoundments are designed to contain the one percent exceedance probability event (100-year event) plus 3 feet of freeboard.

11. All storage impoundments have side slopes of 3 to 1 and are 30 feet deep.

The objective of the SPAW modeling was to help design a land application system that: (1) maximizes evapotranspiration; (2) minimizes surface runoff; (3) minimizes percolation below the rooting zone; (4) minimizes the irrigated acreage required; and (5) minimizes the required volume of the storage ponds while maintaining a one percent probability that the design pond volume will be exceeded during the operating life of the facility.

SPAW modeling was performed at both the Dewey and Burdock sites. A composite of the soil properties at each site was created for use in the model using analytical data from three test pits from each site. Test pits 1, 2 and 5 were used for the Dewey site and test pits 8, 9 and 10 were used for the Burdock site. The composites were created by taking the averages of the gravel, sand and clay fractions and the dry bulk densities for each depth interval for the three test pits at each site.

The SPAW modeling assumed that the facility will operate on a year-round basis for 15 years. Twenty-eight years of daily precipitation, temperature and evaporation data from January 1, 1980 to December 31, 2007 were used to create 28 unique and equally likely simulations of the process water balance. Each simulation used 15 years of sequential climatic data corresponding to the 15 years of operation of the facility. The climatic data intervals used for each of the 28 simulations are shown in Table 1.2-5.

Field simulations using the SPAW model were run using each of the 28 climatic data intervals shown in Table 1.2-5. The results of these field simulations were used as the input to pond simulations for the same 28 climatic intervals. The result was a daily pond volume for each day of the year for each of the 28 15-year simulations.

The pond volume with a 1 percent exceedance probability during a 15-year operating period was estimated as follows. First, the average pond volume for each day during the 15-year operating period for the 28 simulations was calculated. Then, the pond volume for each day of the 15-year period with a 1 percent exceedance probability was calculated using the Gumbel Extreme Value distribution, which resulted in 5,475 possible values. The greatest of these 5,475 values was then selected as the maximum possible volume with a 1 percent exceedance probability during a 15-year period.

Table 1.2-5: Sequential Water Balance Simulations

Simulation No.	15-Year Climatic Data Interval

28	01/01/2007 to 12/31/1993

1.2.3 Model Results

Field Model Results

Based on the SPAW modeling, the irrigated area at the Dewey site would be 315 acres. Pumping at Dewey would occur for 24 hours every day from March 29 to May 10 at a rate of 297 gallons per minute (gpm); from May 11 to September 24 at a rate of 653 gpm; and from September 25 to October 31 at a rate of 297 gpm.

The irrigated area at the Burdock site would also be 315 acres. Pumping at Burdock would also occur for 24 hours on every day from March 29 to May 10 at a rate of 297 gpm; from May 11 to September 24 at a rate of 653 gpm; and from September 25 to October 31 at a rate of 297 gpm. The annual summaries of the SPAW field modeling results for the twenty-eight 15-year simulations at both the Dewey and Burdock sites are attached.

Pond Model Results

Based on the assumptions listed above (Section 1.2.2), the model results showed that the total irrigation storage pond volume having a 1-percent exceedance probability is 216 acre-feet at both the Dewey and Burdock sites. An additional 31 acre-feet of capacity was added to the ponds at each site, for a total pond capacity of 247 acre-feet. This additional capacity acts as contingency storage for days at the beginning of the irrigation season when weather conditions may limit pumping for land application. Four single-lined impoundments (ponds), each with dimensions of 465 feet x 465 x 30 feet deep and a capacity of 61.8 acre-feet, will be operational at any given time at both the Dewey and Burdock sites, providing a total capacity of 247.2 acre-feet at each site. This capacity includes the volume with a 1 percent exceedance probability, plus 3 feet of freeboard. A double-lined radium settling pond with leak detection will also be constructed at each site, with an operational storage of 39.2 acre-ft, which includes sufficient capacity for the settling of barium sulfate and radium, the total volume of which over the 15-year operating life is estimated to be 0.036 acre-feet. In addition, there will be a Central Processing Plant (CPP) pond at the Burdock site. The CPP pond will be 362 feet x 362 feet x 25 feet deep including 3 feet of freeboard, with a total capacity of 36.2 acre-feet.

The annual summaries of the SPAW pond modeling results for the twenty-eight 15-year simulations at the Burdock site are attached. The climatic conditions and pond inflow rates are the same for both sites, and therefore the SPAW pond modeling results are also the same.

Runoff Model Results

Runoff from irrigation return flows and from rainfall falling on the land application areas will be conveyed to collection areas at the edges of the land application areas and allowed to evaporate. The quantity of this runoff was calculated by the SPAW model and entered into a monthly water balance to determine the required volume of these collection areas. The following equation summarizes the monthly water balance:

$$S = RO + P - E - I$$

where:

S = storage required

RO = runoff from the 315-acre land application area due to irrigation and precipitation

P = precipitation falling directly on the runoff collection area

E = evaporation from the collection area

I = seepage from the collection area

The water balance was determined using a spreadsheet model that calculates the cumulative storage required at the end of each month during the 15-year operating life of the facility. Water balances for five potential 15-year operating periods were simulated for both the Dewey and Burdock sites, using five 15-year periods with the highest total annual precipitation amounts from the 28 years of available climatic data. The results showed that a 35-acre collection area at the Burdock site would have an average of 1.3 inches of standing water at month-end during each month of the 15-year operating life of the facility, and a maximum of 30.5 inches of standing water at month-end, which occurred during a single month over the 15 years. At the Dewey site, a 35-acre collection area would have an average of 0.13 inches of standing water at month-end during the 15-year operating life of the facility, and a maximum of 8.8 inches of standing water at month-end, which also occurred during a single month over 15 years. The difference in storage required at the two sites is due to the higher permeability of the soils at the Dewey site. The soil permeabilities used in the water balance were based on permeability values determined from laboratory testing of the soils from the on-site test pits.

Assumes seepage is 0.00 for January, February, March and December due to frozen soils
Trial is for bare soil, 314.5 acres irrigated area

Permeability value is geometric mean of three available permeability values from Burdock test pits, see
G:\102\00279.02\Data Info\DB Land Application-Irrigation\Dewey-Burdock\Soil Hydr Props\Dewey_Burdock_Soil.xls

Assumes seepage is 0.00 for January, February, March and December due to frozen soils
Trial is for bare soil, 314.5 acres irrigated area

Permeability value is geometric mean of three available permeability values from Dewey test pits, see
G:\102\00279.02\Data Info\DB Land Application-Irrigation\Dewey-Burdock\Soil Hydr Props\Dewey_Burdock_Soil.xls

				5.48		17.06	44.00		7.23	

Assumes seepage is 0.00 for January, February, March and December due to frozen soils
Trial is for bare soil, 314.5 acres irrigated area

Permeability value is geometric mean of three available permeability values from Dewey test pits, see
G:\102\00279.02\Data Info\DB Land Application-Irrigation\Dewey-Burdock\Soil Hydr Props\Dewey_Burdock_Soil.xls

Assumes seepage is 0.00 for January, February, March and December due to frozen soils
Trial is for bare soil, 314.5 acres irrigated area

Permeability value is geometric mean of three available permeability values from Burdock test pits, see
G:\102\00279.02\Data Info\DB Land Application-Irrigation\Dewey-Burdock\Soil Hydr Props\Dewey_Burdock_Soil.xls

Assumes seepage is 0.00 for January, February, March and December due to frozen soils
Trial is for bare soil, 314.5 acres irrigated area

Permeability value is geometric mean of three available permeability values from Burdock test pits, see
G:\102\00279.02\Data Info\DB Land Application-Irrigation\Dewey-Burdock\Soil Hydr Props\Dewey_Burdock_Soil.xls

Assumes seepage is 0.00 for January, February, March and December due to frozen soils
Trial is for bare soil, 314.5 acres irrigated area

Permeability value is geometric mean of three available permeability values from Burdock test pits, see
G:\102\00279.02\Data Info\DB Land Application-Irrigation\Dewey-Burdock\Soil Hydr Props\Dewey_Burdock_Soil.xls

Assumea seepage is 0.00 for January, February, March and December due to frozen soils
Trial is for bare soil, 314.5 acres irrigated area

Permeability value is geometric mean of three available permeability values from Burdock test pits, see
G:\102\00279.02\Data Info\DB Land Application-Irrigation\Dewey-Burdock\Soil Hydr Props\Dewey_Burdock_Soil.xls

Assumes seepage is 0.00 for January, February, March and December due to frozen soils
Trial is for bare soil, 314.5 acres irrigated area

Permeability value is geometric mean of three available permeability values from Burdock test pits, see
G:\102\00279.02\Data Info\DB Land Application-Irrigation\Dewey-Burdock\Soil Hydr Props\Dewey_Burdock_Soil.xls

				4.86		16.82	44.00		26.41	

Assumes seepage is 0.00 for January, February, March and December due to frozen soils
Trial is for bare soil, 314.5 acres irrigated area

Permeability value is geometric mean of three available permeability values from Burdock test pits, see
G:\102\00279.02\Data Info\DB Land Application-Irrigation\Dewey-Burdock\Soil Hydr Props\Dewey_Burdock_Soil.xls

Assumes seepage is 0.00 for January, February, March and December due to frozen soils
Trial is for bare soil, 314.5 acres irrigated area

Permeability value is geometric mean of three available permeability values from Burdock test pits, see
G:\102\00279.02\Data Info\DB Land Application-Irrigation\Dewey-Burdock\Soil Hydr Props\Dewey_Burdock_Soil.xls

General Operating Assumptions		
1 Production objective	1,000,000	# of U3O8 per year
2 Ave. wellfield design based on # yellowcake per sq ft of ore reserve, equals:	1.60	lb/sq ft
3 ISR recovery efficiency of:	0.75	recovery efficiency
4 First Year production rate	0.91	pounds/yr/sq ft
Average grade of producted water (ppm U3O8)		
5 Area required to meet production objective (online all the time)	911,458	sq ft
	21	acres
6 Area per pattern	10,000	sq ft/pattern
7 Number of online patterns required to meet production objective	91	patterns
8 Number of online Production Wells required to meet production objective	91	production wells
Assuming 20 gpm/production well, total production flow rate equals:	1,823	gpm
Assuming 350 days/yr pumping, average U3O8 grade to meet production objective equals:	130	ppm U3O8
If total flowrate limited to 4,000 gpm, average grade to meet production objective equals:	59	ppm U3O8
9 I/R Ratio	1.6	inj wells/prod wells
10 Number of online Injection Wells required to meet objective	146	injection wells
11 Number of online Production Wells per Header House	18	production wells/HH
12 Number of HH required to meet production objective	5.1	HH
13 Number of Perimeter Monitoring Wells per Header House	2.0	monit wells/HH
14 Number of Internal Monitoring Wells per HH (1 upper +1 lower)	2.0	monit wells/HH
15 Number of Compliance Wells per HH (1300 LF spacing)	0.6	comp wells/HH
16 Subtotal # Monitor wells per HH during production	4.6	total mw/HH
17 Total # Monitoring wells per 1MM # produced during production	23.4	total MW

Byproduct Waste During Operations

Restoration					-		
RO waste and IX waste	Assume costs included in CPP	0			-		
Well Field waste	Assume 1 drum/wk = 7.5 CF/wk	390	CF/yr	7.00	2,730	2,167	4,897
PPE	Assume 1 drum/wk = 7.5 CF/wk	390	CF/yr	7.00	2,730	2,167	4,897
Decon waste	Assume 1 drum/wk = 7.5 CF/wk	390	CF/yr	7.00	2,730	2,167	4,897
					-	**Subtotal**	**14,690**

* Assume Transport to Andrews, Texas @ 710 miles from Site. Assume $3.50/loaded mile with 20 CY load, and $1.85 /unloaded mile. Thus, $2,485 per 20 CY.
Therefore, use $5.35 * 710 = $3,000 per 20 CY.

Restoration Operating Assumptions

Description	Quantity	Units
General Operating Assumptions		
1 Production objective	1,000,000	# of U3O8 per year
2 Ave. wellfield design based on # yellowcake per sq ft of ore reserve, equals:	1.60	lb/sq ft
3 ISR recovery efficiency of:	0.75	recovery efficiency
4 First Year production rate	0.91	pounds/yr/sq ft
Average grade of producted water (ppm U3O8)		
5 Area required to meet production objective (online all the time)	911,458	sq ft
	21	acres
6 Area per pattern	10,000	sq ft/pattern
7 Number of online patterns required to meet production objective	91	patterns
8 Number of online Production Wells required to meet production objective	91	production wells
Assuming 20 gpm/production well, total production flow rate equals:	1,823	gpm
Assuming 350 days/yr pumping, average U3O8 grade to meet production objective equals:	130	ppm U3O8
If total flowrate limited to 4,000 gpm, average grade to meet production objective equals:	59	ppm U3O8
9 I/R Ratio	1.6	inj wells/prod wells
10 Number of online Injection Wells required to meet objective	146	injection wells
11 Number of online Production Wells per Header House	18	production wells/HH
12 Number of HH required to meet production objective	5.1	HH
13 Number of Perimeter Monitoring Wells per Header House	2.0	monit wells/HH
14 Number of Internal Monitoring Wells per HH (1 upper +1 lower)	2.0	monit wells/HH
15 Number of Compliance Wells per HH (1300 LF spacing)	0.6	comp wells/HH
16 Subtotal # Monitor wells per HH during production	4.6	total mw/HH
17 Total # Monitoring wells per 1MM # produced during production	23.4	total MW

		100x100 Grid			
Wellfield Maintenance (per MM # produced)					
# Production wells		91	prod wells		
# Injection wells		146	inj wells		
Well maintenance (assume $500/well)		119,000	$/yr		
Replacement of submersible pumps (say 10%/yr @ 2,000 each)		18,000	$/yr		
# Header houses (per MM # produced)		5.1	#HH/yr		
Header House maintenance	9,500 per HH	48,450	$/yr		
Restoration Assumptions and Cost					
Years to Reclaim wellfields per 1M pounds of U3O8 recovered (see Operating Cost)		0.89	years		
Well Field and Treatment Operating Cost				Electricity	111,000
Treatment Chemicals (see Operating Cost)		8,500	$/yr	Chem	8,500
Treatment Maintenance (see Operating Cost)		49,000	$/yr	Maint	249,681
Treatment Power (see Operating Cost)		17,000	$/yr		
Water Supply Power (see Operating Cost)		43,000	$/yr		
Water Supply pump replacement (10% of supply pump costs)	75000	7,500	$/yr		
Well Field Power (extraction and injection) (see Operating Cost)		51,000	$/yr		
Well maintenance ($300/well)	300	71,000	$/yr		
Submersible pump replacement (10% of well field pump costs)		18,000	$/yr		
Well Field Piping Maintenance (assume 50,000/yr)		50,000	$/yr		
Header House					
Replacement meters, gages, and equip (see Operating Cost)	10,700 /HH	54,181	$/yr		
Land Application					
Power Cost (see Operating Cost)		-	$/yr		
Maintenance Cost (see Operating Cost)		0	$/yr		
Restoration Operating Cost		**-**	**$/yr**		
Stability Monitoring/Decommissioning					
Equipment Decommissioning (see Decommissioning worksheet)					
Wellfield Decommissioning					
Unit cost per well (assume ave depth of 650 feet)					
5" diameter casing =		0.136	CF/LF		
Average well depth =		650	LF		
Cubic ft per well =		88.4	CF		
Cement grout cost =		9.00	$/CF		
Cement grout cost/well		795.60	$/well		
contractor labor w/ equipment = 4 crew-hr/well @ $125/hr = $500.		500	$/well		
Total abandonment cost/well (rounded) =		1,300	$/well	Expend	81,667
Monitoring wells	#wells = 140	182,000	$LS		
Production and Injection wells	#wells = 237	308,100	$LS		
Piping, power, and HH (see Decommissioning worksheet)		-	$LS		
Total Wellfield Decommissioning		**490,000**	**$LS**		
Well Decomm Cost per 1M# U		**81,667**	**$/M# U**

Restoration Costs
Dewey-Burdock Project
Powertech (USA), Inc.

Byproduct Waste During Operations							
Restoration					-		
RO waste and IX waste	Assume costs included in CPP	0			-		
Well Field waste	Assume 1 drum/4 weeks = 2 CF/wk	104	CF/yr	7.00	728	674	1,402
PPE	Assume 1 drum/4 weeks = 2 CF/wk	104	CF/yr	7.00	728	674	1,402
Decon waste	Assume 1 drum/4 weeks = 2 CF/wk	104	CF/yr	7.00	728	674	1,402
					-	**Subtotal**	**4,206**
* Assume Transport to Andrews, Texas @ 710 miles from Site. Assume $3.50/loaded mile with 20 CY load, and $1.85 /unloaded mile. Thus, $2,485 per 20 CY. Therefore, use $5.35 * 710 = $3,000 per 20 CY. Decon truck cost = $500/20 CY							

Restoration Costs by Year
Dewey-Burdock Project
Powertech (USA), Inc.

	Environmental Monitoring	Number	Quantity	Units	Rate ($)	Cost ($/yr)	
Met Station	Assume 1 met station for Site	1	12	visits/yr	200	2400	
Water Qual							
	20 metals, mercury, alk, Cl, SO4, NO3, Fl, EC, pH, and TDS (Test America) @ $350 (w/shipping) spec, Th, U, and gross A/B (Test America) @ $550 (w/ shipping)						
	Baseline: Six quarterly samples from each perimerer + interior well + 1 production well per 8 acres for 1 year. Add 20% for QA/QC. Assume full analyte list (see above) at $900/sample, plus $100/sample for data packages, shipping, and expendibles - $1,000/sample.	6	24	wells/yr	1000	145,833	$/MM#
	Production A: Sem-Annual sampling from each perimeter + interior well during production. Add 20% for QA/QC. Assume 50% of full analyte list = $500/sample.	2	24	wells/yr	500	24,306	$/yr-production
	Production B: Bi-weekly sampling from all perimeter + interior wells, plus 20% for QA/QC. Analytes are parameters that can be tested in CPP lab, so only cost is for expendible supplies - say $10/sample.	26	24	wells/yr	10	6,319	$/yr-production
	Period between end of production and start of restoration: Assume same as Production A and Production B.					30,625	$/yr-transition
	Restoration A: Same and Production A.	2	24	wells/yr	500	24,306	$/yr-restoration
	Restoration B: At end of restoration, production, perimeter, and interior wells, plus 20% for QA/QC, are sampled for full analyte list.	1	134	wells	1000	133,681	$/MM#
	Stability A: Same as Restoration A for one year.	2	24	wells/yr	1000	48,611	$/yr-stability
	Stability B: Same as Restoration B following Stability monitoring.	1	134	wells	1000	133,681	$/MM#
	Compliance: Assume annual sampling from all compliance wells in mined areas until closure is certified. Use 6 wells per 1M# recovered. Assume analytical cost is $800/sample.	1	6	wells/yr/M#	800	4,800	$/yr-cumulative
Radon	CPP (10 dose buttons quarterly)	4	10	buttons/qtr	50	2,000	$/year
	Satell/Well Field (5 dose buttons/quarter)	4	5	buttons/qtr	50	1,000	$/year

APPENDIX 5.2-B

WELL COMPLETION REPORTS

POWERTECH WELL COMPLETION REPORTS
(2007–2008)

DB-GW675

Location Marietta

Construction Details

Total Depth	14.4’
Screen Inverval	4.4 – 14.4’
Sand pack	3 – 14.4’
Bentonite	1 – 3’
Cement	0 – 1’
Distance from surface to top of casing	2.5’

Water Level ~9’ below surface

Lithology

0 – 4 ft	fine to med grain sand, tan color, mostly quartz and feldspar, some dark minerals (5%)
4 – 9 ft	poorly sorted, coarse sand, few small pebbles
9 – 12.5 ft	poorly sorted, coarse sand, mostly quartz and feldspar with dark minerals (10%), some pebbles, wet
12.5 -14.4 ft	dark gray, fissile shale

DB-GW677

Location south of Putnam house

Construction Details

Total Depth	14.5’
Screen Inverval	4.5 – 14.5’
Sand pack	3 – 14.5’
Bentonite	1 – 3’
Cement	0 – 1’

Water Level ~9’ below surface

Lithology

0 – 4 ft	med tan, sandy silt
4 – 6 ft	sandy silt
6 – 7.5 ft	cobbles in silty sand, poorly sorted
7.5 – 9 ft	tan, silty sand
9 – 12.5 ft	wet, tan, very fine grained sand
12.5 -14.5 ft	dark gray, fissile shale (Belle Fourche Fm)

DB-GW678

Location along Pass Creek west of Burdock

Construction Details

Total Depth	14.5’
Screen Inverval	4.5 – 14.5’
Sand pack	3 – 14.5’
Bentonite	1 – 3’
Cement	0 – 1’

Water Level ~8’ below surface

Lithology

0 – 9 ft	very fine grained, red, silty sand
9 – 14 ft	dominantly vfg silty sand with 1” beds of med to coarse sand (did not penetrate shale)

Mr. George L. Coates
Star Route
Edgemort, South Dakota

Re: ConRoy #1 State
NWSW-24-7S-1E
Fall River County, South Dakota
Permit No. 370

Dear Mr. Coates:

Your August 28 letter has been received in which you mention you want to convert the above oil test to a water well for agricultural use.

The oil test was plugged September 10, 1964. The bond was released January 26, 1965. The State Oil and Gas Board no longer has jurisdiction over the test hole.

Approval to complete the oil test as a water well should be obtained from the Water Resources Commission, State Office Building, Pierre, South Dakota. Their phone number is Capitol 4-5911, Extension 343. Mr. Joe Grimes is the Chief Engineer.

The test was drilled to a depth of 2,467 feet. The surface casing consisted of 487 feet of 8 5/8-inch pipe cemented with 275 sacks of cement. The formation tops as picked by the company geologist are:

Dakota	50	Minnekahta	1397
Lakota	237	Minnelusa	1470
Sundance	540	2nd Converse sand	1525
Basal Sundance sand	854	3rd Converse sand	1655
Spearfish	894	2nd Leo zone	2060

Cement plugs were placed at approximately the following depths:

420-600	1640-1715
835-910	2060-2135
1460-1525	

If I can be of further help, please contact me.

Sincerely,

Earl Cox

RE: Tubbs 1-35 Well
SE/4 SE/4 Sec 35-7S-1E
Fall River Co., SD
CWO 9506

Dear Mr. & Mrs. Tubbs:

You have requested the use of the referenced abandoned well as a potential freshwater well for which an acceptance and release is required under ARSD Article 74:10:04:02:(4)(c)(i), a copy of which is attached hereto.

Ceja hereby grants and conveys the well to you in its present condition as reflected in the attached plugging report, provided you sign and return this letter releasing Ceja of any further responsibility or liability for the well prior to its conversion for actual use as a freshwater well. You further understand that you shall assume responsibility for the well and all attendant liabilities and accept the well in its present condition without any warranty or representation of its fitness for your intended use.

Thank you for your cooperation and assistance. If we may be of further assistance, please call me at 1-800-331-3359.

Yours very truly,

Paul G. Rose

______, Secretary

INSTRUCTIONS

General: This form is designed for submitting a complete and correct well completion report and log on all types of lands and leases to either a Federal agency or a State agency, or both, pursuant to applicable Federal and/or State laws and regulations. Supplemental instructions by local Federal and/or State offices will govern the use of this form.

If not filed prior to the time this summary record is submitted, copies of all currently available logs (drillers, geologists, sample and core analysis, all types electric, etc.), formation and pressure tests, and directional surveys, should be attached hereto, to the extent required by applicable Federal and/or State laws and regulations. All attachments should be listed on this form, see last blank.

If this well was directionally drilled, show both the location at the surface and at total depth from nearest lines, where possible; also show the locations at the top and at the bottom of any zone for which production data are reported in space 33, and any zone open for injection or disposal. Use this reverse side if more space is needed. (MD-Measured Depth, TVD-True Vertical Depth)

*Indicate which elevation is used as reference (where not otherwise shown) for depth measurements given in other spaces on this form and in any attachments.

If this well is completed for separate production from more than one zone (multiple-zone completion), so state in the correct space and show the producing interval, or intervals, top(s), bottom(s) and name(s) (if any) for only the zone reported in the blanks under PRODUCTION. Submit a separate completion report on this form for each interval (zone) to be separately produced.

"Sacks Cement": Attached supplemental records for this well should show the details of any multiple stage cementing and the location of the cementing tool.

SUMMARY OF POROUS ZONES:
SHOW ALL IMPORTANT ZONES OF POROSITY AND CONTENTS THEREOF; CORED INTERVALS; AND ALL DRILL-STEM TESTS, INCLUDING DEPTH INTERVAL TESTED, CUSHION USED, TIME TOOL OPEN, FLOWING AND SHUT-IN PRESSURES, AND RECOVERIES

(iv) Cement must be circulated to fill at least a 100-foot interval, of which at least 50 feet must be above the shoe of the surface casing; and

(v) A cement plug must be set at the surface as prescribed by the secretary;

(b) Wells without production casing:

(i) All aquifers, salt zones, and fluid-bearing formations must be sealed or separated with individual cement plugs, circulated to fill at least 100 feet of hole. Each individual cement plug must be at least 50 feet above the top of the following formations, as specified by the secretary;

(A) Fort Union Group
(B) Hell Creek Formation
(C) Fox Hill Formation
(D) Niobrara Formation
(E) Greenhorn Formation
(F) Newcastle Sandstone
(G) Inyan Kara Group
(H) Sundance Formation
(I) Minnelusa Formation
(J) Madison Formation
(K) Interlake Formation
(L) Red River Formation
(M) Deadwood Formation

(ii) Cement must be circulated to fill at least a 100-foot interval, of which at least 50 feet must be above the shoe of the surface casing; and

(iii) A cement plug must be set at the surface as prescribed by the secretary;

(c) Conversion of a well to a water well:

(i) When a test hole may safely be used by the landowner as a potential freshwater well, the operator must follow the plugging procedures set forth in this section to the base of the objective freshwater strata, if applicable. The surface owner must give a signed release to the operator before the conversion is made;

(ii) The well must then be constructed to meet specifications established in article 74:02.

Source: SL 1975, ch 16, § 1; transferred from § 52:02:04:02, effective July 1, 1979; 13 SDR 129, 13 SDR 141, effective July 1, 1987; 14 SDR 50, effective October 4, 1987.
General Authority: SDCL 45-9-13.
Law Implemented: SDCL 45-9-11, 45-9-15.

74:10:04:03. Temporary abandonment of a well. Written approval must be obtained from the secretary for the temporary abandonment of a well. A well that is not completed with production casing may not be temporarily abandoned and must be plugged immediately. A well with production casing may not be temporarily abandoned for more than six months, unless the operator is granted an extension by the secretary.

Skull Creek - based on Darton's geol map

1. shale, light gray, very silty	0 - 37
2. clay, light gray, bentonitic, waxy, with muscovite mica flakes; piece of sandstone, fine, tight, white	37 - 80
3. shale, light gray, silty	80 - 100
4. sandstone, fine white, with white clay in interstices (looks like Unkpapa)	100 - 140
5. sandstone, fine to medium, incoherent, subrounded; some white clay and one siderite pellet. Water sand.	140 - 146
6. clay, gray-brown to light gray, waxy, translucent	146-147
7. sandstone, like sample 5	147 - 150
8. sand, as above, and much waxy clay	150 - 156

Fall River

Inyan Kara

This is an odd set of samples. Samples 1 to 3 do not look like Skull Creek. 4 could be Muddy, but looks like much of the Unkpapa where it is white. Nos. 5 and 7 look like Dakota but not like Newcastle (Muddy). Nos. 6 and 8 look like Morrison, but could be Fuson.

I still think it is a Dakota section, but the next time I get down that way, I shall stop for a look at the surface.

WELL DATA FROM TENNESSEE VALLEY AUTHORITY

Table 2.5.2-1

Summary of Wells Within a Four-Mile (6.5 km.) Radius of the TVA Burdock, No. 1 Shaft Site

Well No.: Based on the Federal system of township and range. Each township within the project area is assigned a letter in consecutive order beginning with "A" in the northeast corner and ending with "F" in the southern part. Similarly, wells are numbered in consecutive order within a township--for example: B-1, B-2, etc. Location: Number based on township, range, section, 1/4 section, and 1/4 section. Aquifer: Qa, Quaternary alluvial deposits; Kf, Cretaceous, Fall River Formation; Kl, Cretaceous, Lakota Formation; Jm, Jurassic, Morrison Formation; Js, Jurassic, Sundance Formation; Trs, Triassic, Spearfish Formation; PmK, Permian, Minnekahta Limestone. Depth: Given in feet (ft.) and meters (m.) below land surface. Use Rate and Flow Rate: In gallons per minute (gpm) and liters per second (l/s). Elevation of Land Surface and Elevation of Water Surface: In feet (ft.) and meters (m.) above sea level. Superscript a indicates flow rate less than 1 gpm. Superscript b indicates estimated water surface elevations.

Well No.	Latitude	Longitude	Location	Aquifer	Depth (ft)	Depth (m)	Use Rate (gal/min)	Use Rate (l/s)	Flow Rate (gal/min)	Flow Rate (l/s)	Elevation Land Surf. (ft)	Elevation Land Surf. (m)	Elevation Water Surf. (ft)	Elevation Water Surf. (m)	Remarks

INTEROFFICE CORRESPONDENCE

Company Silver King Mines, Inc. Date August 3, 1979

To: R. M. Caywood

From: Keith E. Andersen Subject: Quarterly Burdock Area Water Levels

Attached are quarterly measurements of Burdock Area water well flow rates and water levels. Wells numbered 135 - 143 are new wells or wells added to our monitoring program by request. Wells numbered 200 - 216 are probable Sundance wells located east of the Burdock Area.

In an effort to obtain all possible information, several measurements of questionable accuracy were made as noted below.

Well No.	Problem
2	Leaking around casing
4	Leaking around casing
7S	Measuring point changes
13	Pipeline use affects flow
33	Measuring point changes
35	Measured inside cylinder drop pipe
36	Leaking around pipeline fittings
37	Measured inside cylinder drop pipe
40	Two wells at different elevations piped together
41	Pump had been operating
42	Leaking around pipeline fittings
52	Measuring point changed
53	Measured through cylinder drop pipe
56	Casing broken out
98	Casing leaking
113	Measured inside cylinder drop pipe
114	Measured inside cylinder drop pipe

Water quality data on these wells is not yet complete.

Keith E. Andersen

Keith E. Andersen, Chief Engineer

F 300 B 4M 7-78

85	Tubbs Ranch	Domestic	415	K f	Pumped to house, Reported SWL 30'
86	Tubbs Ranch	Stock	360	K f	Pump jack, SWL reported 20'
87	Tubbs Ranch	Appears abandoned	380	K f	Plugged with wooden plug. Reported SWL 20'
88	Tubbs Ranch	Appears abandoned	320	K f	Two wells, one may be caved in, one SWL 10'
89	Porter & Benton	Pipeline	860	K 1	Submersible pump, runs extensive pipeline. SWL reported 5'
90	B. Childers	Stock	Oil test		SWL 1.0 '
91	Carl Reutter	Stock	150	K f	Windmill SWL 34'
92	Carl Reutter	Domestic	298	K f	Pumped to house, Keene reports SWL 132'
93	Bob Runge	Domestic	200	K 1	Two wells, couldn't measure, Keene reports SWL 80'
94	Bob Runge	Stock	200+	K 1	Flows 0.75 gpm.
95	Wayne Jackson	Pipeline	~~800~~ 860	K f	Barely flows, submersible pump to pipeline.
96	Billy Stearns	Domestic	560	K 1	Flows 4.8 gpm.
97	Billy Stearns	Stock		K 1	Uranium test cased to 200', hole reported to be caving below that & sealing off flow. Flows.
98	Billy Stearns	Stock	Oil test		Leaking around top of casing, flows est 2 g
99	Gerald Darrow	Domestic	420	K 1	Flows 2.2 gpm.
100	" "	Stock	530	K 1	Flows 150 gpm (by Hodson) apparently used to fill water trucks.
101	" "	Morresy Pipeline	665	K 1	Pipeline serves ranches west, submersible pump. Hodson reports flow 3 gpm.
102	Lloyd Darrow	Domestic	267	K 1	Will flow est. 100 gpm. Sells water
103	Lloyd Darrow	Stock	350	K 1	Flows 1.3 gpm.

Water Wells in Edgemont Project Area

Map #	Owner	Use	Depth	Probable Aquifer	Remarks
104	Lloyd Darrow	Stock		K l	Jensen jack, reported SWL 6'
105	Lloyd Darrow	Stock		K l	Not visited, reported SWL 8 to 10'
106	Lloyd Darrow	Stock			Flows 3.5 gpm.
107	Earl Darrow	Domestic	90	K f	Pumped into house, flow est. 1 gpm.
108	Chet Taylor	Domestic	90	K f	Taylor lives here part of time. Info reported by Earl Darrow. Flow rep. 1 gpm
109	Vivian Cook	Domestic	220	Kl	Reported SWL 22'
110	Vivian Cook	Stock	240	K l	Reported SWL 30'
111	Vivian Cook	Not used	100	K f	Owner plans to develop, reported SWL 5'
112	Miles Spencer	Stock	120	K f	Windmill, couldn't measure.
113	Miles Spencer	Stock			Back up well for Spencer pipeline.
114	No info				Forest Service.
115	Bud Hollenbeck	Domestic		K f	Flows 3 gpm.
116	Bud Hollenbeck			K f	Flows 2.75 gpm. At Dewey Post Office.
117	Bud Hollenbeck	Stock Garden			Submersible Pump. SWL 27'
118	Bud Hollenbeck	Stock	Oil test		Flowing out of casing at ground level
119	Bud Hollenbeck	Stock			Submersible pump, reported SWL 6'
120	Forest Service	Stock			Pumpjack, couldn't measure.
121	Bud Hollenbeck	Stock	430	K l	Will flow?? est. 100 gpm.
122	Bud Hollenbeck	Stock			Windmill, couldn't measure.
123	Bud Hollenbeck	Stock			Pump jack, couldn't measure.
124	Bud Hollenbeck	Stock			Not visited, reported windmill.
125	Bud Hollenbeck	Stock			Casing rusted off. Flows at ground level.
126	Francis Carr	Domestic		K l	Flows, couldn't measure.
127	Francis Carr	Stock	Oil test	K l	Casing rusted off, flows at ground level.

Water Wells in Edgemont Project Area

Map #	Owner	Use	Depth	Probable Aquifer	Remarks
128	Francis Carr	Stock	Oil test	K l	Couldn't measure, est. 5 gpm.
129	There are several old oil tests in this area. The ones reported as being used are reported above. There appears to be some flow from some of these but the casings seem to be bad and all there is now are some marshy areas. Some use of water for stock from these is possible.				
130	Dick Miller	Domestic	155	K f	?
131	Dick Miller	Stock	110	K f	Flows 0.8 gpm
132	Dick Miller	Stock	300	K l	Flows est. 2gpm
133	Dick Miller	Stock	300	K l	Not contacted. Information from Keene
134	Roberts & Daniels	Stock	860
